**H F CONDITIONS**

During the last month, from January 15<sup>th</sup> to February 13<sup>th</sup> the solar flux has  
varied four points from 70 to 74. Currently, at 0303 UTC on 13 February 2008, the  
SFI is at 72 and is predicted to remain at that level tomorrow.

There were 21 days WITHOUT sunspots and 7 days WITH sunspots during this  
period. In the ARRL Propagation bulletin Tad Cook K7RA is suggesting that in the  
period from February 16 to 26 we are unlikely to see any spots although from  
February 27 to March 1 sunspots may reappear.

While we have talked about the fact that the sunspots in a “new” cycle have a  
reversed polarity from those of the “old” cycle, I recently stumbled onto a “law”  
discovered in the early 1900’s by G. H. Hale that indicates reality  
is more complex. What Hale found was that when the sun is well spotted, during  
the declining part of a cycle, the spots in the northern hemisphere have one polarity  
while those in the southern hemisphere of the sun’s disc have the opposite polarity.  
As the cycle then continues beyond the minimum and spots begin to appear at high  
latitudes in say the northern hemisphere of the sun’s disc they have the opposite

polarity of those that were formerly present in that hemisphere. Thus what is usually called a Solar Cycle is really ½ of a cycle because it has to undergo another ½ of a cycle to return to the same pattern of polarities as it first had. In other words, a REAL Solar Cycle is 22 years on average rather than the usually sited 11 years! Of course all of this has nothing to do with how real HF conditions are..... There has been no HF activity at W9LYN this past month but PERHAPS with the ARRL CW DX Contest this weekend, February 16-17, there will be some activity here. Good luck if you get in the Contest!

73 DE Bill – W9LYN
