"For those who are interested in telegraphy, for those who would like to learn it, for those who love it, and for those who want to improve their skills in it."

William G. Pierpont NØHFF

The art and skill of telegraphy is unique. The psychologists who have seriously studied those who have developed this skill have been fascinated and challenged to try to understand it. Isn't the very idea of being able to communicate your thoughts to another by means of intermittent tones something intriguing in itself?

The Art and Skill of Radio-Telegraphy currently has the following known translations and web adaptations

French: Third Revised Edition: Editor Maurice Colombani-Gailleur F6IIE, http://f6iie.free.fr/booknØhff.htm or http://www.uft.net/titre_web.htm

Danish: Editor: Jens Henrik Nohns, ØZ1CAR, Laerkevej 11, DK-7441 Bording, Denmark

Japanese: 2nd Edition 1997, Published 1Ø August 2ØØØ in Tokyo by the JARL A1 Club, Editor: Atzu Taniguchi, JE1TRW, with assistance of other JARL 1A Club members.

Introduction

would probably never have been done at all if I had not been so eager to learn the telegraphic code, but made such a terrible flop of it. I just barely qualified for a license in early 193Ø, and for a very long time could not receive it well enough to really enjoy using it. Like most others in those past days, I memorized the "dots and dashes" from a printed table.

A good teacher might have helped, but.... If only I could have had just the following key paragraph from the QST article of gotten me off on the right foot:

"The first step in learning the code is to memorize the dot and dash combinations representing the letters. They must not be visualized as dots and dashes, however, but rather should be "auralized" as sounds. There is no such word as auralized, but if there were it would express the correct method of grasping the code. The sound dit-dah (meaning a dot followed by a dash) in the head telephones must impress your mind directly as being the letter "A" for instance, without causing black dots and dashes to float before your eyes for an instant. This is a point that always troubles beginners, but if you learn from the first to recognize the sounds as letters immediately without reverting to dots and dashes, you will make much better progress..."

More succinctly: "Don't try to teach the Ears through the Eyes." (Wireless Press 1922)

I was not alone in making this first false step: very many others did it that way, too, and probably some today still do. It was and is can't seem to get beyond it.

The second mistake, even in learning by hearing, is in hearing

July 1923, it would have at least counts them mentally. (It is wise indeed for the beginner never to hear code characters sent at speeds below about 13 wpm.) These two errors largely account for getting stuck at higher speeds also - they mean we have not really learned the characters.

> Today, there are many tapes and computer programs available which teach the Morse code in ways that avoid making either of these basic errors. This book has been written to share the results of this research of the literature also including talks with skilled operators - with those who want to learn or teach the Morse code, or to improve their own skills. It majors on the methods that have proved most successful, but also discusses some which should be avoided. It offers guidance for those just beginning, and help for those who are stuck and want to improve. It also tells how those who are proficient and those who are experts operate.

Some history and related items are included in the later chapters for those who are interested in telegraphic communication. My hope is that you will find it not only interesting but helpful. This is a "How To" book, not a scientific treatise. Source credits for the inevitable reason why most individual items have rarely been people who start this way get noted. Many a contribution has stuck at some speed, around ten come from multiple sources. Most words per minute or less, and of the significant sources are listed under Sources.

"I have never known a person who was truly proficient with code the characters sent so slowly that to dislike it: on the contrary, the the learner tends to analyze each more proficient they are, the more one into dits and dahs, and even they love it." The Morse code is a

means of communication, a new built up from simple, available way to enjoy expressing yourself.

William G. Pierpont NØHFF

Is the Radio-Telegraph Code Obsolete?

Outsiders and some of those looking into Amateur radio often ask this question: "Isn't the Morse code obsolete? Hasn't modern technology displaced it?"

Back in 1912 nobody balked at learning the code: it was simple then - if you didn't know the code you couldn't even listen and understand, much less communicate by wireless.

work-a-day problems and com- code. pletely absorb one's attention.

to voice. Besides this, the equipment required, both transmitting and receiving, is much simpler and smaller, uses less power, and in an emergency can often be

parts.

These factors have not escaped the Russian communists. They were also deeply impressed with the reliability, simplicity and lower cost of equipment for code communication and ease in maintaining it. (In the same line of thinking, their military radio gear has all been vacuum tube type to avoid potential damage due to radiation.) Therefore, through the years they have popularized and promoted learning the Morse code and developing skill in its use. It was included among their civilian "sports" activities. Contests and prizes were offered to the best and fastest op-But today, however, it refuses to erators. This would assure them of lie down and die. In addition, they have realsignals penetrate distance, and go ized that Morse is an effective through interference and static means of communicating during where voice signals can't hack it. periods when the enemy is jam-This is why low power (QRP) en- ming. There are other advantages thusiasts find that it is far superior also. It uses the narrowest signal bandwidth, which for amateur use means more channels are available within a band. It has the best signal-to-noise ratio, and in addition, an operator can soon learn to separate (mentally "filter") signals which are very close together Not very long after this beginning by differences in pitch, speed and style of sending.

Learning the Morse Code -An Overview

Where we are going

If you are looking for any magic, any secrets, any tricks here - or hypnotism - you won't find it. What we do offer is just practical, time-tested working methods, which together take advantage of all that has been learned over the years about how to teach and learn the Morse code efficiently and well.

George Hart, long time code expert with ARRL put it this way: "The greatest obstacle in learning code is the method used."

Ted R. McElroy, teacher and long time code speed champion said that any normal person can easily achieve 25 wpm. This is an easily achievable and reasonable goal. One who can handle this speed comfortably is a good operator.

The original American Morse code of 1845 was designed to telegraph wires any and every kind of written message or information in letter-perfect, number- you want to learn it - you can. perfect, and punctuation-perfect form. It was recorded as a wiggly line on a strip of paper tape to be read or interpreted by eye. Very soon the operators discovered that they could read the recorder's noises accurately by ear, and so in time sounders slowly began to replace the recorders.

operators became so skilled that they began to chit-chat easily over the wires among themselves, much like radio amateurs do today when they "chew the rag". That kind of freedom should be our goal - easy, natural use of the code to communicate, similar to the way we read and talk. That's where we are headed.

The code is not a new language. It is the language you already know, "written" in sound patterns instead of patterns of ink on paper it is your own language. You will learn to "read" by ear the language you already read so well by eye.

This is lesson one, it is most important always to think of it this way:- Every Code Letter, Number And Symbol Is A Unique Pattern Of Sound.

Psychology teaches us that when we start to learn something new, if we think of it as being easy, it will be easy. The best teachers never hint or suggest that there is anything hard about it, and their students learn it quickly, usually within a week or two. They also communicate: to transmit over the make learning it fun. We learn much faster that way; so think of learning it as fun - enjoyable. If

> Our foundation is the alphabet, numbers and punctuation marks. Learn these *sound patterns* so well that when, for example, you hear "dahdahdit" you immediately recognize it is "G". This is basic, but don't stop there. Code is to communicate: and we don't talk in letters, but in words. Words are

while we are still learning to mas- plans are ter the alphabet we can begin to recognize small common words, such as "the" and "of" as words when we hear them.

When we first learned to read, we could already talk, but reading was something new, and it took a little effort to learn. At first we had to spell out each word, then _ try to figure out how to pronounce it, and then remember what we had already deciphered while we tackled the next words until we had laboriously "read' the whole sentence. The beginning stage of learning the code is that way, too, but it doesn't need to stay that way. Words are written as strings of letters, one letter after another. But we don't read them that way - we read the word. If we couldn't spell we couldn't write either - or else we would have to use hieroglyphics. Words must become our units of thought in Morse because words make sense and they are easy to remember.

Reading code, like reading print, becomes much easier and faster when we have learned to **recog***nize words* instead of spelling them out as strings of letters. A good reader reads words, and even strings of words at a glance. We can learn to do it: many, many others have. We are hardly conscious of the letters which spell out the words we read so easily now. Our attention is focused on the *thoughts* written in print, and our reactions are to the ideas expressed.

When we begin to reach this stage with Morse code, we are begin-

our smallest thinking units. Even ning to become proficient. So our

- to learn the alphabet of sound patterns so well that we recognize each letter instantly, then
- to learn to recognize most of the words we hear as words, and finally
- to learn to listen to the stream of code as we would to someone speaking to us in words and ideas.

That is proficiency, whatever the speed is being received. We can learn to do this at any speed. Our goal should be to learn to use the code so that it becomes easy and natural, like the way we read and talk.

Chapter 1

How to Go About it Efficiently

This Chapter Is A Summary To Prepare You To Learn

Learning the Morse code is acquiring a *New* set of *Habits*. It is a skill subject governed by the same principles that apply to learning tennis, shorthand, typing, playing a musical instrument, etc. Regular consistent, repetitive *Practice* sets in concrete what we do and the way we do it.

Some people have managed to master the Morse code without any help. Others have used poor methods, and both have all too often given up when they came to a plateau, short of proficiency. Today methods are available which almost guarantee success, and a number of fine courses exist using these methods.

These principles are outlined below and will get the beginner off on the right foot and bring him to proficiency. If you are one who has gotten stuck, use them to get back on track. They offer the is coming next, can cause us to most rapid way to success in learning the telegraph code and achieving a real mastery of it.

Prepared - prepared with the right Attitudes, and with knowing What to do and **How** do it. This can mean the difference between success and failure.

Your Attitude toward learning is crucially important: It is essential **Preparation** for success.

- Have a "Can-Do-It" attitude, because it is easy to learn. If you don't tell people that learning the code is hard, it won't be. If you really want to learn it, you can. Approach it as if it were impossible to fail. Motivate yourself.
- Keep a Relaxed Atmosphere, free of tension, pressure, any sense of hurry and anxiety.
- Enjoy the learning process itself.
- Picture Yourself Being Successful.

Comments:- Whenever we think of anything as "hard," it creates a stumbling block, and that tends to discourage us. - Most people find that competition during the initial stages hinders learning. In actual reading and copying code, any anxiety or undue concern about "getting it all", or too intense interest in what is being received, or trying to outguess what miss out some of what follows. -People who do things well do not struggle with them. - "Relaxed receptiveness" works.

Get your first impression of the code characters by Listening to them - By Ear the way you will actually use them.

Throw away all printed code charts and any trick memory methods people offer - they will inevitably slow you down and may even discourage you as you Instant recognition is what we advance.

Comments:- The reason learning the code by eye or by mental pictures will slow you down is because our visual and auditory (hearing) memories are completely separate from and unrelated to each other. Trying to learn by charts or "sound alikes" slows down learning because they make us go through one or more needless steps each time we hear a character. In both cases the mind has to go through a conscious analytical or translation exercise for each signal. See Chapters 4 and 13

From the very first learn to hear each code character as a *Unit Of Sound*, a whole pattern, a rhythm.

At first each character should be sent fast enough, preferably from about 18 to 25 wpm or even faster, for us to hear it as a unit, and with a wide space before and after it. Never, never try to analyze it into parts. This is most important.

The Code Character Is The Letter.

For example, when you hear "didah" recognize it immediately as being "A" - you are "hearing" the letter "A." Associate the code signal with the printed letter so intimately that when you hear or If you listen to poorly sent code diately pops into mind. Our mind by forcing it to try conmental "equation" should be sciously to figure out what the immediate, like this:

"didah" "A". "A" "didah". strive for.

These Four Principles Are Absolutely Essential.

Concentrate On One Aspect At A Time.

For example, don't try to learn to block print or typewrite while you are learning to copy.

6. Learn To Receive The **Code** Accurately - this is our primary goal.

In receiving we must wait until each character or word has been completely sent before we can correctly recognize it. We must develop that patient, receptive state of mind that allows us to recognize each character instantly and accurately as soon as it has been completed.

7. Listen only to Accurately Sent Code.

Accurate character formation timing - is essential for efficient learning. Proper spacing between letters and words is as important as the correct formation of the characters themselves, and becomes even more important as speeds increase. At first it is best to listen to cassette tapes, computer or keyboard generated code. If you have a teacher follow his advice.

think of the one, the other imme- you will needlessly distract the characters are supposed to be. (Once you become proficient, you can learn to read such sending.) Likewise, in the early stages static and other signals.

Sending becomes relatively easy after you have a good timing Teachers differ on the best way to sense. It is also easier because you start out. Your teacher or course know in advance what is coming may start out having you write next. However, listening to your down each character as you hear own sending at too early a stage it. Either way is to help you assomay hinder learning because the ciate the sound with the letter or characters are not being sent ac- number. Sooner or later you will curately enough.

Plan for regular daily Practice Periods.

The learner needs to know exactly What he is going to do and When. Make them Short Enough to prevent fatigue, boredom or discouragement. Space them widely enough apart to let what you have gained sink in. Practice is building habits: let's practice only what is right.

We all have our ups and downs. Some days we will do better than others- this is just a part of normal you. It's better to put off prac- help. There are several exercises ticing to advance at a "bad" time which can help us. See Chapter 8. (if you're tired out, sick, down in the dumps). Make practice material enjoyable - interesting in variety and content.

Listening And Copying.

If you are studying alone, start out by just listening without writing down anything. (See section 2 above.) Listen to the signal and say the name of the letter or number out loud immediately after you hear it. After you get familiar with all the letters and numbers so you feel somewhat comfortable recognizing them, then practice writing down each

of learning avoid all distracting letter or number immediately afnoises, and interference, such as ter hearing and recognizing it (that's called "copying"). See Chapters 7 and 8.

want to be able to do both.

In any event, as skill increases we are going to have to learn to copy. At first it will be letter by letter. But that will prove to be too slow as our skills increase. - In order to advance we need to learn to copy behind: that is, to be writing down what has been heard while listening to what is being sent. This only needs to be a syllable or two or a word or two behind, even at high speeds - this takes the pressure off. For many people it seems to develop almost automatically as they practice and learning, so don't let it discourage use the code, but most of us need

> Some hams started out copying everything, and have become so tied to their pencils that they just can't seem to understand anything without writing it down first. That is an awkward way to converse! "Throw Away Your Pencil" is good advice. It forces us to learn to receive by just listening. (I knew a ham who for over 6Ø years couldn't receive without a pencil. When he became almost blind, he had to learn - and he did, very quickly!) We need to learn both ways - to copy and to listen. So what if we miss a few

get the gist of it. Remember even the best operators sometimes miss a word or two.

1Ø. We gain **Speed** by the right kind of practice.

It depends on more and more nearly instant recognition, first of characters, then of words and finally of larger units of speech and thought. To advance in receiving speed we must push ourselves. Short bursts of speed work best even as short as a single minute at a time, rarely more than 3 to 5 minutes. If you want to increase your speed, listen to code at a speed faster than you can get it all, and pick out all the words you can recognize. In copying, pick a speed just a little too fast for at least part of your practice time. receive is up to you. Set your own goal.

Remember, however, that the goal is *Communication* of intelligence, not just speed for the sake of speed.

11. We advance in skill after mastering the letters, numbers, etc., by learning to Hear Words As Words instead of just strings of letters

This is the second stage in mastering the code. Most people find it already beginning even while still working to master the alphabet, as they recognize little words like "of" and "the." We need to extend it to include at least the words we use most often. Start by deliberately listening for and practicing them until they become

words here or there? - We can still units of sound and recognitionheard and sent as words.

> Our list of 1ØØ most common words is a good place to begin (see end of Chapter 4). Practice them by listening to them, and as you send them over and over until when you think of the word it just seems to flow naturally as if you were reading or writing it. Practicing with these common words seems to help the brain begin to learn to handle many other words as words, too. We can extend this skill by practicing some of the word prefixes and suffixes, such as pro-, per-, com-, -ing, tion, etc. The bigger the units of sound we recognize as units the easier receiving and sending be-

This kind of practice, with careful How fast you want to be able to regard for spacing and timing, will prevent forming the sloppy habits some hams have fallen into as they run the letters of short words together like a single complex character, and also when they forget to space between words. These things make reading and copying very difficult, and as speeds increase, can make it almost impossible.

12. **Over-learning** is the secret of real proficiency.

It is achieved when we simply receive and send in code with the freedom and ease that we have when we talk, read and write, virtually unconscious of the code as code at all. One old-time operator, when asked whether the other ham had used a certain word, replied that he didn't remember the actual word - he had the thought clearly in mind, but he couldn't remember the exact word. That is code once they have learned it. a mark of the expert.

From the language arts we learn how people become fluent in a foreign language. It is by Repetition, saying the same sentences over and over, with or without little variations until they become automatic. Or in other words, Just Becoming So Familiar With It that it seems natural. When we reach that point, no matter what our top speed may be, we have achieved a mastery of the code. It is a goal well worth our efforts.

These points are expanded and explained in considerable detail in the rest of Part I. If you are a be- It Is To Be Enjoyed ginner, go immediately to Chapter

Chapter 2 will help you under- Principles of Skill Building stand the why's of our recommendations, and the further chapters are yours to grow on.

Experience has shown that under normal conditions, like riding a bicycle, once your code skill has reached about 13 or more words per minute (wpm) it is never forgotten. You may become "rusty' but the skill quickly returns.

How Long Will It Take Me To Learn

Those who have been taught using these principles and methods have taken from a minimum of one week to an average of about three up to eight weeks to achieve a satisfying 15 to 2Ø wpm working speed. People are different in background, in attitude, in approach to learning, in interest, enthusiasm and drive, and in what they want to do with the Morse

All of these factors play a part in the time it will take. The main thing is to want to learn it, whatever time it may take, to realize that it is EASY and to want to USE it when it has been learned. Those who just learn it to get a license, and do not intend to use it will probably find it not be useful within a year or two. Yet some of them may even find that it is interesting and really interesting and worth while. Some have done this already. Read Chapter 12.

Code is a pleasure when we know it well. It is an art worth acquiring.

Chapter 2

and Attitudes for Success

Two factors are of primary importance in building a skill efficiently:

- Right Mental Attitudes
- Practice doing it the right way from the very start

Neither one alone will maximize success.

Here we apply these principles to learning the code.

We Are Building A Set Of Habits

Skill-building is generating a set of habits. It begins at the highly conscious levels of letter by letter, number by number, etc. Gradually your skill will build up sometimes by sudden breakthroughs. More and more subconscious control takes over and

there will be less and less conscious thought about it. As it becomes more and more automatic, your full attention can be given over to the thought content, the ideas expressed while listening, and when copying, you may find yourself thinking of something altogether different.

like playing golf, a musical indesired, and which work automatically and without conscious effort when we want them. It has an active and a passive aspect. It is active when we are sending, and passive when receiving. The goal is to become able to receive and send as easily as the expert does he is comfortable about it - just as if he were carrying on a conversation

Skill is developed by consistent, repetitive practice of materials which become increasingly familiar (letters, numbers, words, punctuation, etc.). Never practice error! Only correct practice is beneficial. This builds confidence and proficiency.

learning to receive (which is listening with understanding or by writing it down). Ultimately conscious thinking of the code must be eliminated, and we respond automatically. Then sending will be easy, too.

Anything

- That produces tension or
- Requires thinking interferes both with the learning

process and with using the code.

Relax

In the process of learning, minimize tensions by having a clear picture of where you are headed the goal, what you are going to do and the steps you're going to take Telegraphy is a skill somewhat to get there. Take little steps, one at a time - small enough that you strument, typewriting, etc. It is know you can do each one. Inlearning a set of habits which can troduce new material little by litbe called into operation whenever tle, in small enough bites that you don't feel overwhelmed - yet not so slowly that it becomes boring. Provide enough variety to keep it interesting, and introduce new items as soon as you are ready.

> Take it easy. Especially in the early learning stages keep things at low key, comfortable and free from strain. Some people learn faster than others, so it is a good idea to avoid all competition (because it tenses us up) while you are learning the new game of the A B Cs in sound - learn at your own rate.

Avoid all unnecessary tensions because they tend to distract our attention. That also means being we need to get rid of all kinds of Our major focus will be on distractions, worries, duties and anything else that makes us feel concerned so that we can concentrate on what we are doing. That makes learning easy.

> Relaxation and confidence go hand in hand. Each promotes the other. Easy does it. When you know you are doing the right thing in the right way, this promotes confidence, and that makes learning easier.

how to relax. They generally begin by learning to pay attention to specific parts of the body one after another, such as starting with the toes and feet and going upwards, to legs, abdomen, chest, arms, hands, neck, head, face, eyes, etc. As you concentrate on each part, first tense it so that you know what tension feels like, and then deliberately release that tension and recognize what relaxing it feels like. With practice this can be done in a relatively short time, an almost all at once action. Breathing can also be coordinated so that deep inhalation, followed by exhaling easily is thought of as producing relaxation. Try it

Develop A Good Mental Attitude

Anticipate success. "Nothing succeeds like success." In order to succeed you must first believe that you can do it. Everything possible must be done to guarantee success at every step, and to prevent any sense of discouragement or failure from developing. Never even suggest that learning it could be hard. - As for errors, ignore them, except that when they are persistent they merely point out where more practice is needed. With the right approach and right practice you can't fail.

Mental attitude is critical: We should approach every aspect of learning with interest, enthusiasm and a positive "can do" outlook. Anyone who really wants to learn the code can learn it. If you have the ambition to learn it you have the ability to do it. A feeling of confidence is vital to achievement,

There are many schemes to learn and must be guarded carefully. how to relax. They generally be- "If you think you can, you can."

Don't fight negative attitudes, such as anxiety, fear, worry and doubt. But if you do feel any of them, admit it, and then ignore it and let it die of inattention.

Make learning fun. Enjoy the learning process itself. When I am so eager to learn that I can hardly wait to get going, how receptive I am and what energy surges up! Watch how youngsters play and learn as they play. They are good models: they're relaxed and having fun. They don't pay any attention to mistakes. Imitate them and enjoy learning the code. That makes it even easier, and more enjoyable.

Stage One Learning The A B C's

Our first impressions are the strongest and most long-lasting. So be sure your very first exposure to the code signals is right by hearing it. Otherwise, it may raise a roadblock, a "plateau", somewhere along the path which will require us to go back to line one in order to advance.

- Code is sound heard with the ears, not read with the eyes.
- Listen from the very beginning only to perfectly sent code until you have mastered it.

To advance rapidly your mind should hear only consistent patterns of sound. This hammers it into the mind, hearing the same character formed exactly the same way each time. Poor quality code

will tend to confuse the mind, terest and enthusiasm start it up distract your attention, and slow down your rate of learning.

A recent study by Dr. Henry Holcomb of Johns Hopkins University on learning new skills says that after first learning "how to It is impossible to try NOT to atdo it", engage in routine activities of some other kind to allow a five traction. Attention to it will only hour time period in which no other new skill learning is attempted. He claims that experiments show that it takes abut six hours for to permanently transfer the new learning from the front brain to permanent storage in the rear brain. This is something to try and see if it helps speed up Morse code learning. He also added something we already should know: that it takes lots of practice to learn rapid, complex, and precise hand motor-skills.

Develop a sustained attention. Attention to the thing in hand is the starting point of all learning.

- Identify what needs attention, and
- Do that, focusing on it alone,
- Do it early in the practice period when energy levels are highest.

The more interesting the subject is, the easier it will be to concentrate on it. Direct your mind to go where you want it to go by stimulating your interest.

A stop-start technique will help you gain control of your attention span and lengthen it. It works this way: When attention lags, don't fight it, but stop all thoughts and clear the mind, then let your in-

again fresh and naturally. If the distraction is one which you can identify, clear the mind by either settling it at once, or by setting it aside to handle later.

tend to something, such as a dismake it more distracting.

It has been suggested that the mind resembles a portable built-in computer, but it is far superior. It can do feats of information processing and recall unequaled by the largest computers. First we must debug it and get rid of any old bad attitudes about the code and replace them with a positive "can do" and "enjoy it" outlook. Next, feed it with a "lookup" table of soundequivalents for the various characters, and we're in business: an automatic motor-response to the audio signals: we hear didah and immediately visualize and write "A". Don't put an artificial limit on your speed of comprehension.

Stage Two - Practice

Once the fundamentals are well in hand and our speed is increasing, we need to apply pressure in short bursts in order to advance. At this stage begin with a few minutes of warm-up at a comfortable speed, then use familiar materials to try for a burst of speed for a minute or two at first. Keep it short to minimize the discomfort. Then drop back to a more comfortable speed, and you will find the mind responding faster.

Avoid practicing when too tired, ill, or all upset and distracted -

and it may even discourage you.

It takes time for associations to develop. Be patient and learn at your own rate. Some days will be better than others for various reasons. Progress will not be uniform, but that should not bother you because you know about it beforehand. When you feel good ment.

As these processes improve, conscious thinking tends to drift away, and we need to keep the mind focused on what we are doing in order to advance. But ultimately, conscious thinking must be completely eliminated and response become automatic (we no longer even think of the code itself). That's proficiency.

More About Attitudes For Success

Achieving our best performance in any skill, including telegraphy, is a personal matter. We need to:

- observe how we think and act when doing our best, and then
- learn to control those attitudes and actions so that we can use them when we want them.

While each of us behaves as an individual, there are definite principles which will greatly speed up our success as we adapt them to ourselves. At first they may seem

little or nothing will be gained awkward and unproductive, but if we stick with them - improvement will begin and grow much more rapidly than without them. Attitudes are critical, and for best results we need to individualize them, fit them to our very own needs. We can lay a foundation for positive attitudes if we do the following:

and can enjoy it you will advance Feel confident, it promotes learnthe fastest. On days when you ing. If you have an opportunity, don't feel very good it is best not watch a skilled operator, observe to push, but rather to work at a how calmly and quietly he goes comfortable level which will give about it. He is in no rush, and is you some sense of accomplish- not concerned about missing anything. He goes about it just as if it were everyday listening and talking. Instead of filling the mind with problems, worries and concerns, occupy the mind with the way things should be done. In learning, build confidence by taking one firm step at a time, telling yourself, "I can do this".

> Build a sense of achievement, that good feeling of doing something well. As a guard against frustration be sure to provide periodic successes, with simple little rewards for each. Keep a record of the goals and your progress: as you see your progress it will help build positive attitudes. Give yourself some little reward after each practice session.

Picturing Success Is Strong **Preparation For It**

Mentally Practice the thoughts, feelings and actions necessary for good performance and you will greatly speed up achievement - a valuable tool to accelerate learning. How can it be done? In a general over-all way you may

picture yourself quietly and with- yourself receiving and sending out strain listening to the incom- while you are doing other things ing signals and easily recognizing (such as driving, walking, workthem as the printed or spoken ing, etc.), not making any parletters and words they represent, ticular effort to fill in details. and as sending well-formed characters without hurry or strain. Picture yourself doing it, and doing it well, like an expert. It helps to have a real model in mind. Watch or imagine a skilled performer (a telegrapher if you can find one) at work. He isn't in any hurry. He isn't flustered or concerned, he just does it and enjoys it. Repeat and rehearse this picture often in your mind.

There are at least two ways to use cil writing on the paper. Feel a this tool. One is to sit back and sense of satisfaction of doing it relax and deliberately form the right. All this is preparatory and supportive of real practice, not a substitute for actual practice by doing. The goal we seek is for the it time to grow

Chapter 3

Part I: Laying the Foundation

Let's Begin With The A-B-C's

Many good ways have been developed through the years for learning the telegraph code easily and efficiently. Our purpose here code. The sound is the letter. is to present the very best ways to learn it efficiently and to compress the learning time to a minimum. It is too bad that so many hams have learned poorly and as a result have not been able to enjoy it as they should. The trouble often began by imagining that code would be hard to learn, or by learning it in an inefficient, or round-about way, such as visually, by sight, rather than by sound or by "sound a-likes".

Everything depends on how you set about learning it. It is much more difficult to go back and unlearn something which was learned wrong, than it is to learn the right way from the very start. Trying to learn by oneself without

with!. It may also be used to help ficult later. Most learning trouble pert wrote: The most difficult students at Harvard were those who had learned the code by themselves by practicing alone without guidance.

use of the code to be as natural The Telegraph Code is an Alphaand easy as talking, reading, writ- bet of Sound. It is Learned by ing. These mental images take *Hearing it*. When we learned to some real effort and practice. read our language, it was, or Don't expect instant results, give should have begun by first learning to recognize the ABC's by sight. Telegraphy begins by learning to hear and recognize the ABC's by sound. This difference is important. Code is learned by hearing it. Recognition of the sound patterns is the name of the game. For example, when you hear "didah" as "A," without translating, you are thinking in There is no reason ever to see the code in written form.

So Throw Away Those Code Charts, All Of Them, Burn Them

Saying the letter immediately, or writing it down immediately, each time the ear hears it is one of ways to build the code habit quickly. We need direct association between sound and letter. Anyone who is stuck on a "plateau"because of having learned it visually or some other inefficient way will have to learn it all over again by sound. It is unfortunate that some still try to learn it this way. To teach it this way today is inexcusable.

It is Easier Than You Think Someone wrote: "Mastering the

two." You aren't learning a new it clearly, smoothly and readably. language, a whole dictionary full of strange words, and sentences where the words are all scrambled up. You are just learning how to "read" your own language By Ear instead of by eye. It's no big job.

Almost anyone who can learn to how didn't make it, or got stuck read can learn the code. There is no such thing as a normal person who wanted to learn the code and "learned", and start over with the couldn't. "I can't learn the principles set forth here, and you code" nearly always translates into "I won't commit myself to the time necessary to learn it," or that a person doesn't really want to, even though he may think he does. Age, whether young or old, and intelligence, bright or dull, are no barriers. Youngsters of four or five can learn quickly, and oldsters of 9Ø have succeeded, too. You wouldn't want to admit that a four-year old or a 9Ø-yearold could outdo you, would you? It doesn't require superior intelligence, just right application.

Most handicaps, such as blindness or even deafness, have not stopped those who want to learn. Deaf people have been able to learn and receive using their fingers on the driver of a speaker at 3Ø wpm or on the knob of an electromagnetically driven "key knob" bouncing up and down at 2Ø wpm. (Even some people with dyslexia have been able to learn to a useful extent.) It is easy if you really want to learn it and then go about learning it in the right way. Any person of reasonable intelligence can learn the

art of code communication is ten Morse code and become a very times easier than learning to talk - good operator, able to copy it which you did by about the age of with a pencil at 25 wpm and send

> There is no real justification for the statement that "some people just can't learn the code." (They don't want to.) It's a matter of motivation, the secret of learning any skill. If you are one of those who tried in the past and someat 8 or 1Ø or 12 wpm, take heart. Forget what you previously will succeed.

Some Naturally Learn Faster than Others Just as some people have a knack for learning to play golf or tennis more quickly than others, so some have a special knack for learning the code. They catch on more quickly, but most of us take a bit longer. Kids tend to pick out the sound patterns easily and naturally without straining so they learn very fast

Motivation

Nothing beats enthusiasm to learn. Stir it up - eagerness. Couple that with determination, and failure is impossible. If you want to so badly that you can almost taste it, you can do it. If you are teaching it, take advantage of any latent fascination with the idea of a special skill, secret code for communicating: many youngsters have it and maybe some older people, too. One lady who later became a code teacher said she got started because "the code sounded like fun." One man found that the very idea of comby intermittent tones is most fascinating.

A sense of achievement and the intimacy found in code communication make the effort a lot of fun. CW is fun if you take the time to learn and to be comfortable with it. Be motivated. Fix it in your mind that you can do it. Then relax, be willing to learn at your own rate, refusing to compare yourself with others, and take time to enjoy the learning process. Make it fun. (Trying too hard or trying to hurry, can create a Learning the Morse code is much kind of tension which impedes like to learning to read by eye. progress.) Take it easy. Keep it Learning to read print has several leisurely. The more you expose stages of skill level. yourself to it and the less hard you "try" the better and faster you'll become good at it. You can't help succeeding. Enthusiasm and determination will win out

The sudden beginning of WWII required a lot of operators in a hurry. Many Amateurs volunteered and served directly as operators or by teaching new recruits. However, the attitude of some recruits was often indifferent or poor: many of the draftees had no desire to learn it, and some even disliked the idea of learning it at all. No wonder it took them so long to learn and a good many failed! -- Telegraphy is a skill whose success depends greatly upon the right attitude.

One school teacher demonstrated the code, both sending and receiving. The class got so fascinated that they managed to learn 14 characters in that one class period. No-code students, no longer

municating his mind to another under pressure to certify code ability, who have been given "a taste of the way it used to be" by listening, have often gotten interested and want to learn at least a few letters to start with. Quite a few no-code licensees, after having had some fun operating, are looking for more ways to enjoy ham radio: the Morse code doesn't look so abstract to them as it did before.

Learning The Morse Code Is Similar To Learning To Read

- First we learned to recognize the individual letters, and could slowly spell and sound out words.
- Next we began to recognize and read many common short words as words, instead of having to spell them all out.
- Before long we learned to recognize short phrases ("of the", etc.) and some of the longer words as whole words.
- Finally an expert reader can read whole clauses, sentences and even a paragraph as a unit of thought, almost at a glance.

This gives us a clue as to how to go about learning and improving Morse code skill. The essence of code learning, like language learning, is familiarity - that means over-learning. That is, learning to the point where it has

become automatic, without unique sound pattern, just like thinking about what you are doing: the dits and dahs, or even the words. The highest skill comes when you just seem to be hearing words and sentences and you are conscious only of the ideas being expressed - that makes communicating: a most worthwhile and gratifying goal. But it doesn't mean you have to become a speed demon.

The Morse A B C 'S Are Patterns Of Sound

The Best Beginning is by Listening

Phase One

Learning To Recognize Each Letter And Number As Soon As code sound-patterns. Start trainthe alphabet of sound. This is the the ear hears the sound pattern goal of stage one of code learning, building the foundation. The code must be thought of as sound patterns.

If you have been having trouble, the moment you begin to think of code solely in terms of sound patterns, you will have made much progress. A printed letter is a combination of lines which form a shape. But children are not taught to recognize the letters of the alphabet by pointing out the various lines which make it up, they are taught to recognize each letter as a whole, at a glance. The same principle applies to learning code: each letter and number is a unit of sound, a unique sound pattern, a rhythm, different from every other letter or number. Each code character has its own

spoken vowels and consonants do.

Morse code is **Sound Patterns**, to be heard by the ear. Any method of learning the code which uses the eyes (such as charts for "memorizing the code", or some other scheme (such as rhymes or "sound-a-likes", etc.) will prove to be a serious handicap to later progress. This is because it makes "translate", something we must do consciously. If you have been doing it by thinking: "dit dah stands for 'A', "you have been thinking in terms of separate "dits" and "dahs". That makes it hard. So forget that there are such things as "dits" "dahs" and learn to think in We Hear It: the "A-B-C's" of ing yourself like this: every time "didah" you think "A", and if you are copying, the hand writes "A". With some practice, like a good operator, you will find that the character just seems to come to mind from nowhere. Proceed directly from sound pattern to letter, with no intermediate interpretation of any kind. It may help if you whistle or hum the sound patterns.

Part II: Laying the Foundation

Delayed Perception And Instant Recognition

There is one obvious difference between reading by eye and reading by ear. While a printed letter is to be instantly recognized at a glance, a code character cannot be recognized until the whole pattern has been heard - at the

end of the short time it takes to out. That pattern or rhythm of the send it. We must "hear it out". letter is to be heard as a whole

Two important factors are involved here:

- The characters must be heard at speeds that compel us to hear them as complete patterns, as wholes, not as strings of "dits" and "dahs" Tests have shown that speeds of at least about 13 wpm are required and that faster speeds are preferable (18 -25)
- The spaces around them must be long enough to make the sound patterns stand out clearly and distinctly

This is why the so-called Farnsworth method is used: making the spaces between characters quite wide at first and then gradually reducing them to the standard. Combining these two ways we soon recognize that, while we know that the sound patterns are formed of "dits" and "dahs", we never allow ourselves to try to analyze or count them.

We must first consciously listen to each letter until the mind accepts it as a complete letter without there being any kind of conscious thinking about it involved. We forget the dits and dahs and just listen to the patterns, the rhythms. So, the ear's "glance" is a little longer than the eye's - it hears each sound pattern separately because of the wider spaces which separate it from the preceding and following sound patterns.

These spaces are very important they make the sound pattern stand out. That pattern or rhythm of the letter is to be heard as a whole over a short period of time, and cannot be recognized until the whole pattern has been heard as a complete pattern. We must "hear it out" before we can identify it. When we get the sound patterns well fixed in mind it is good to listen to faster and slower speeds and hear the letters roll out.

Listen Only To The Best Quality Of Code

In the early stages it is very important to listen only to the most perfectly formed code you can find. The ear and mind need to get intimately familiar with the rhythm pattern, consistently formed. Poorly sent code gives a sloppy, irregular rhythm which tends to confuse the mind and slow down learning. Don't expect to develop any real speed listening to hash. Listening to poor sending on the radio has sometimes discouraged learners because it distracts the mind by compelling us to think consciously about the details instead of the wholeness. We have to slow down. Listening to poorly sent code defeats the learning process. (Later, with improved skill, you will probably be able to understand most of the poorly sent code. But for now avoid it.) This is also why you should not try to send code yourself until you have a good sense of timing.

Getting Started

There are several ways to introduce the student to the code. One highly effective way to create the

right impressions for the beginner is to dictate a sentence or two, spelling each word out in ordinary letters at about a 20 wpm Teachers disagree on this. Some rate for him to write down, like this:

YOUAREGOINGTOFI NDITISEASYTOLEAR NTHEMORSECODE.

The teacher then assures the students that they will do equally well as they learn the code. "All we are going to do is to change the names of the letters:-- instead of 'Y', that letter is going to sound 'dahdidahdah'," and so on. Now the student is ready to learn the first few letters by sound.

nearly everybody can quickly and meet both goals. No matter recognize the difference between what order is used in teaching, a few words sent at about 2Ø each character must "stand on its wpm, to begin the first session, is own feet," and not depend on word recognition:-- send a simple comparing it with some other word or greeting such as "Hi" and a good-Bye, such as "73." Send each one at say 2Ø wpm half a dozen times until everyone gets familiar with its sound, then send them randomly and have them say the words. Then stick in a different word like "the" see if they protest. Tell them what it is and send it few more times. This can whet their appetite and show that them that it isn't hard those sound patterns really mean something.

For people who are afraid that they can't learn to identify sound patterns, some have suggested that "V" and "B" be compared by sound initially by sending them alternately.

What Characters Shall We Begin With

suggest that taking the simplest characters first (such as E I S H 5, and then E T I M, etc.) helps to build up a feeling of confidence. Others point out that this may lead some students to try to analyze the longer characters, so they recommend beginning longer characters (such as (O 7 Z G, Ø 9 8 J P, or the numbers 1 2 3...). This has the advantage of compelling the student to wait until the whole character is completed before identifying it. Perhaps a good way would be to start with a couple of short letters first, Another good way, because and then go to the longer ones character in order to learn and identify it.

> The important thing, of course, is to hear the characters at speeds high enough that they are heard as complete unified patterns, and preferably at first to present in the same lesson characters which have quite different patterns of sound so that there will be no attempt to compare them

Methods To Go About Teaching

There are at least two ways to start out: a) listening only at first, and 2) listening and writing it down. For those who learn by themselves, one experienced old time teacher wrote: "The beginner should listen to the sounds until he becomes sound conscious. He should not write anything down for a week or two, but concentrate his efforts on recognizing the sounds. He can already write, but he cannot write with any degree of ease, if at the same time he is trying to do something else which he is not familiar with [recognizing code characters].

As a beginner, he would hear a letter, take a short interval of time to decide what it is; with the result that when it comes to him, he quickly tries to write it down and misses the next letter. Wait on learning to write it down until you can recognize the letters as letters, and this confusion will vanish. Learning to read code is recognizing the sounds immediately, that is, the letters." This is wise advice if you are studying by yourself.

Probably most teachers prefer the second approach in a class situation. Such might be, for example, the following (taken from actual teaching procedures):-

The teacher says: "This is F" and then F is sent. Then he says: "Now here it is again. Write it down with your pencil each time you hear it." He repeats it several seconds apart quite a few times before taking up the next letter, which ought to have a quite different rhythm pattern, such as G, introduced in the same way. Then he sends these letters in random order until the students get them right about 95% of the time. Next, he introduces a third

letter followed by random letters learned, and so on for a half dozen or so at a session, however many the students can do without confusion or becoming fatigued or bored. Note: Each one should write or print the way he usually does.

B. The teacher sends a dit and says: "This is a dit. It is the letter 'E.' Now here it is again: write it down each time you hear it. Forget that it is a dit - it is the letter 'E'." Then he simply sends "E" a number of times as the students almost automatically write it down. Then: "Now we will hear the letter 'I'. Listen." He sends 'T.' and says "This is a 'I'. Now here it is again. Write it down when you hear it." And so on through the group for that lesson. After each new letter has been drilled in, there is random letter practice, using all the letters previously learned. Finally, because even for the first lesson he has chosen letters that can be used to construct small words, he sends these words with the instructions: "Now here is a word. Write down the letters just as you did before." He waits a few moments while the class writes it down and says: "Now then, you have copied the word . . ." And so on to the end of the first lesson of 3Ø - 45 minutes. Subsequent lessons follow

this general pattern until the alphabet is completed, etc.

Part III: Laying the Foundation

Most sound recordings for selfstudy introduce each letter something like this: "when you hear 'didah', say "A" to yourself each time you hear it, as soon as you have heard it. Do the same thing for each new character as it is introduced." Then they begin, for example with the first letter 'F': sending dididahdit and saying "F", dididahdit "F," and then follow with a long string of "F's" alone for the student to say "F" after each one, before taking up the next letter.

Whether learning with a teacher or in private study, repetition to the point of familiarity is vital. A teacher can usually judge quickly from student behavior how many repetitions are needed. For the self-study student it is probably good to over-do the number of repetitions of each character before going on, but don't do it thoughtlessly. Some teachers use 2. up to a dozen to two dozen such repetitions of each new character before going on. Since the whole superstructure of telegraphy is built on this foundation - be sure it is solid and secure. Repetition sets in concrete what we practice. Do it wisely. Repetition with attention builds expert skill, making the connection between stimulus and response so strong that the response automatically follows the stimulus.

In these early lessons a little game of "odd-ball" may help. It goes like this: the same character is sent

5 or 6 times in succession, but at one place a different character is sent. The students, who are just listening, not writing, are to hold up their hand when the "oddball" is heard. A few minutes of this can liven things up and give variety. It can be extended to short words, too.

Learning on a one-to-one basis with a good teacher who can tailor each lesson to the student makes possible the strongest initial impressions of the sounds and rhythms of the code characters and to concentrate on any weak areas. The teacher can also safely introduce use of a key earlier than otherwise. Character "echoing"method to reinforce learning:

- 1. Teacher says: "Listen as I send the character" He sends it and says its name as he sends it. "Now listen as I send again and again, and say its name each time as soon as I finish sending it."
- 2. "Now listen and write the letter down each time as soon as I finish sending it."
- 3. "Take your key now and send it back to me each time I send it, and say its name as you send it." It is important that steps 1 and 2 have enough repeats of the letter so that the student has a clear "feel" for the proper timing when he comes to step
- 4. Lastly, The teacher will insist on accuracy of sending.

For those studying alone, there are a number of good code-learning tapes and courses, as well as computer programs which have great flexibility. E.g., a code computer program which can project the printed character on the screen an instant after the character is heard can encourage the student to mentally "see" the letter as soon as it is heard. See Chapter 18.

If some students think that certain characters sound alike, send them cally the alphabet and numbers save you time later. may be covered in a series of no more than five lessons. Everything possible should be done to make learning interesting and fun, and to avoid any sense of boredom or needless tension.. One teacher says: "I write words on the board and the students sound them in unison., It is like directing a choir, a fun class, where everyone feels good about practicing the code.'

copying in use, starting out by copying on a typewriter has the advantage of a better link up between code, brain and typewriter key than between the brain and a pencil. When this stage of learning has been completed, the foundation - quick recognition of every character by its sound pattern - should have been laid, and a speed of at least about 5 - 6 wpm achieved. All the pieces are now in hand for the students to be able to practice with normal English words and sentences, ready to

build up speed and greater confidence by practice. One may then begin to reduce the spaces between words, which will speed up the overall rate of copying.

Every effort should be made to stimulate a sense of success in the student all along the way. This makes learning so much easier and faster. Let them taste success. Forget errors: praise achievements. The goal Is Instant Recognition Of Every Character. That is what the next stage is to carry us forward to. If there are letters you don't recognize quickly enough several times alternately so the now, go back and practice listenreal differences stand out. Typi- ing to them until you do. This will

> A E I O U - vowels first, then some of most frequent consonants, such as T N R S D L H, etc., so that many words can be practiced from almost the first consonant letters learned.

Note: The teacher should explain at each new step exactly what is to be done and why, so the student will know what is expected of him. Back in 1895 some psychologists asked expert telegraphers: "What is the learner's attention mainly directed to as he progresses?" Their answer was:

- 1. At first you hustle to get letters
- 2. Next you look for words
- 3. Later as a fair operator, you are not held so closely to words, but can take in several words, a phrase or even a short sentence as a 'mouthful', and
- 4. Finally as a real expert, you have such automatic perfection that you pay practically no conscious attention at all to the details of the code, but concentrate on the sense of the message, or to transcribing (copying) it while our mind thinks about other things.

Chapter 4

Building The First Floor On The Solid Foundation

Gaining Fluency in Code to a Useful 15 wpm Level

By the time you have reached a steady speed of about 15 wpm you will have a useful and comfortable communicating tool. This will require practice of what you already know, and you will have to push yourself in little spurts to speeds where you cannot get it all at first to reach this goal. Such bursts in speed should be no longer than about one minute at a time, and you will be surprised how effectively this will help raise your receiving speeds.

Instant Recognition

The first secret of increasing your receiving speed is to shorten the time it takes you to recognize each code character as soon as it has been completely heard. The shorter that time interval is, the faster you will be able to receive. Aim to make it instantaneous. If You Do Not Instantly Recognize The Sound Of Any Character, You Have Not Really Learned It **Yet.** (That is the one character you need to practice on until you know it immediately.) The goal of practice and drill from here on is to speed up your recognition of characters, and then of words, to the point where you can both "read" them easily without writing, and copy them down more and more automatically.

Anticipating

In ordinary listening and reading many of us habitually anticipate what the next word or sentence is going to be, and we are ready to jump ahead or help out. Most of us can do this without losing anything that actually comes next: what actually does follow just replaces whatever we anticipated. By contrast, even at high speeds, the code signals are so slow compared with the speed we think that for some of us anticipation can create a severe mental block, causing us to miss out completely what actually comes next. In the very slow speed learning stages this risk is greatest.

If you become conscious that this habit is interfering with your receiving at any point in learning or

later use, you should take imme- International amateur call signs, not in any way interfering with actual reception, the best thing is discouraged if it does not interfere with reception.) A tendency to anticipate does tell us one good thing: we haven't reached out limit yet and can learn to read code faster if we go at it in the right way. (See Chapter 11 for further discussion of this.)

What Kind Of Material To **Practice**

Most of the materials for practice should be in regular English and as *interesting* as possible. Have a variety in every practice period so portance of Repetition. that nothing becomes monotonous. Select the kind of material mon words impressed as units of you intend to be working with as sound to the mind is to repeat you use the code. Other Ways

Several other simple practices can - doing something else - such as help you gain familiarity and into ten minute practice periods, confidence. One of these is to followed by a five minute rests. read road signs and ads you see Three or four such periods per while driving or riding, whistling session are adequate at the early them aloud or mentally to your- stages. They can be lengthened self in code. If you have friends gradually so long as fatigue does also learning, try whistling code not set in. Remember that fatigue back and forth among yourselves and boredom tend to defeat rapid as conversation. There are lots of advancement. other possibilities - find them and make it fun. For example:- The Two-Way Word Game This is a good speed builder, and works this way: the instructor sends a word and student sounds out the word to himself (see phonics, Chapter 7) as the letters follow one after the other to build up the word until a space comes to show that the word is completed.

For example, the instructor sends the word "was". As the student hears W he thinks "w-", then as he hears A he combines them (WA) to think "way", and finally as he hears S and then silence, he thinks the word "was". Then the student immediately sends it back to the instructor. The student writes nothing down. Begin with two-letter words, then four or more letters as the student catches on and speeds improve. Remember that it is a game. Make it fun. Never again will you try just to retain the letters in a word; but

sent. Practice listening to it until putting the sounds represented by the words come as easily and the letters together as they come

Practice

Keep practice sessions short and with some *resting* time in between

Teachers are divided as to whether it is better to major on receiving practice without copying or to major on copying. The best course would seem to be to do some of both. Some teachers insist that the student not copy for some time after initially learning the characters. They prefer for him just to listen. The idea is to build up and strengthen sound pattern recognition without the distraction of writing. Chapter 7 and Chapter 8.)

As for sending practice, it is best not begun until the student knows how good code sounds. The sound patterns need to be firmly enough established in mind that the student can imitate them without the discouragement of hearing his own poor character formation and bad or irregular spacing, and also to minimize criticism. It seems best to defer using a key until a receiving speed of about 1Ø wpm is

the timing and rhythm produce helps speed up its recognition. accurately formed characters and spacings. Aim for it, and don't be satisfied with anything less. (See Chapter 9.)

One good form of early practice to be in unison.

Copying has the advantage of verifying accuracy of recognition and identifying areas needing improvement. In the early stages the use of random groups is best because it avoids anticipation. Listening practice, without writing anything down is of great importance and value. To gain skill this should be done at speeds almost as fast as you can receive by just listening, and with frequent short burst of listening to still faster sending. This will help the mind get used to more rapid recognition.

It has been found that it is receptivity to a stop. grouping which largely determines how fast one can receive "Make code. What doesn't Sense" tends to slow us down. At almost any skill level, random characters will be the slowest, and isolated, unrelated or unfamiliar words come next. The highest receiving speeds are achieved with connected text, and it tends to be receivable at twice or more the speed of scrambled letters. (Even nonsense sentences can be received fairly fast because they

reached. At all times aim for have a familiar pattern.) It is the beautiful, perfect sending, where coherence of a grouping that

There is another factor which we should be aware of. It is this: when we are practicing by listening to the radio and must strain to "get" the signals - because of sending is to listen to a character, weak signals, interference, static or then send it; hear the next and poor sending (trying to figure out then send it, etc. Another helpful a bad combination) or to recall way is for the student and teacher some word previously sent, this to send a short series of words or brings the conscious mind into sentences simultaneously, aiming action, to try to reason things out. As the conscious mind works harder and harder, the receptivity of the unconscious mind tends to cease. This mental friction interferes with advancement in the earlier stages of gaining speed, and may even bring all receptivity to a stop. Whenever you must strain to "get" the signals - because of interference, static or poor sending - to try to figure out something being sent, this brings the conscious mind into action. to try to reason things out. As the conscious mind works harder and harder, the receptivity of the unconscious mind tends to cease. This mental friction may bring all

> **Familiarity** with what is being sent makes learning easier and faster. Words which are unfamiliar to the operator are more likely to be read and copied wrong. Progress is about 50% faster using connected text than words alone. Many more mistakes are made with non-word letter groups which are not words than with normal

Getting Stuck

To have a "plateau" means to be stuck at some speed. It may be just a temporary condition which is passed over with a little more practice, or it may be something that stubbornly refuses to yield. Several different factors may cause the stubborn kind of plateau. A plateau is the result of interpreting the sound as something other than the letter itself. Someone has written that it is the condition" where the conscious mind is fighting o translate, while the subconscious mind is quietly trying to get through and tell you it's got perfect copy." A plateau is a battle in the mind, with the conscious mind trying to translate the dits and dahs and not being able to keep up, while the subconscious mind is quietly trying to get thru and tell you it's got perfect copy.

wpm it usually occurs because they come that from must said one is "translating" the code them this upon great about characters first into some inter- other shall every these first mediate form (such as a mental their could which would there picture) and then translating that before should little people again into the ordinary letters. That is a two-step operation which takes more time than the proper one-step operation does (e.g. "didah" is "A"). Such a situation is often the result of using one of the old and obsolete learning methods Again, when the characters are initially sent too slowly the student tends to count the dits and dahs and analyze them in this way. I have known old time operators who by long practice routinely counted the components of all the longer

characters to identify them at speeds up to as high as 2Ø wpm, or faster! That's the way they learned them, but what a waste of time and effort! Counting and analyzing both tend to keep the conscious, analytical mind involved where it should not be. This will slow us down and tend to bring on needless fatigue. One experienced old timer wrote: "Once you start becoming familiar with [code] sounds as in speech, there are no plateaus.'

The 100 Most Common Words In English

go am me on by to up so it no of as he if an us or in is at my we do be and man him out not but can who has may was one she all you how any its say are now two for men her had the our his been some then like well made when have only your work over such time were with At speeds of around 7 - 100 or so into very what then more will

Twenty short words. Listening to, copying and sending the 1ØØ most common words is good daily practice. Also the 1ØØ words makes good typing practice.

Passing Examinations

Our primary interest here is to help you learn and use Morse code so you can fully enjoy this beautiful mode of communication. Passing exams is of secondary interest, though necessary to obtain full licensing so you can enjoy conversing by means of Morse code on the air. Many students who have started out with the recommended 2Ø wpm minimum character speeds have found that they were able to achieve 13 wpm within as little as a week or two of intense guided practice. It is important to know what to expect in a license examination: the format of an exam, the types of questions asked, etc., so you can practice them and not be surprised. Such materials are available for current examinations from the ARRL and other sources. These things will not be treated here. The only one who fails is the one who does not try again until he succeeds. If this is your problem, learn where your weaknesses lie and practice to You determine where that point is. Many a ham has tried twice, three Don't give up

Chapter 5

Practice To Gain Proficiency

When you have reached about 15 wpm code will have become a useful tool for communication: You will have become an operator.

However, it is pretty slow, but now you have come to feel some satisfaction of mastery, and can see

that to be able to handle somewhat higher speeds will greatly improve your communication skills. How shall we go about it? Mere repetition won't do it We need intelligently directed practice it must be done in the right way. This is what we discuss now.

How Far Do You Want To Go

For the sake of discussion, we may divide advancement somewhat arbitrarily into four stages. which we will call:

- A "good" operator up to about 25 wpm,
- A "skilled" operator up to around 35 - 4Ø wpm,
- An "expert" up to about 6Ø wpm, and
- Over 6Ø wpm a "superexpert."

Each stage should bring increasing personal pleasure in accomplishment up to whatever point you feel satisfied with and have no desire to go further.

overcome them for the next test. Advancing is by "changing gears" like going from" low or more times before he passes. gear" where we recognize characters, to second gear where we recognize small words and some common syllable as units of sound, 3 gear where we have increasing freedom from conscious spelling and sense of increasing pleasure as one hears and sends words pretty much as words, and then finally "overdrive" where we are hardly conscious of spelling except occasional rare words or proper names, and are hardly

conscious of exactly which words bly can too. How? The "pro" in are used, but mainly of the ideas.

Reaching higher speeds will turn out to be easier than you might suppose. It is mostly a matter of determination, right approach and practice, and building on what you already know. Your rate of gain will depend mostly on how you go about it, and will be about proportional to the square of the time invested. So, how far do you want to go? (Remember: it is not speed, but accuracy that counts --. We want to communicate. Time is lost by mistakes, whether in sending or copying.) So take one step at a time, and when satisfied, stop. When we read a book, the *Enjoy* the experience of learning. immediately perceive as rapid recognition. Whenever tance, and permit our subcontends to slow us down.

Word recognition is what makes a proficient operator. The real "alphabet"of the expert telegrapher is largely one of words; it is his "language," and interpreting it is as easy for him as talking and listening. (See "Kinds of Practicing" for an exercise to help develop this.) It cannot be stated too often that: The skilled operator does not hear the dits and dahs, but only the letters, words, sentences. **Relax** and **Enjoy It** We

code is completely relaxed: he knows he can read and copy it, even while doing something else. He hears it like the spoken word and often can even remember it well enough to copy it down later if he needs to. He doesn't get tensed up. He is a good model, whatever speed he has achieved. If you know one, imitate him and keep relaxed and enjoy the challenge of advancing all the while you are progressing. If you don't know any expert code operators, watch any skilled performer, a violinist, a pianist, a tennis player. See how easily he goes about it.

bigger the "bites" we take, the Make each practice period fun. faster we can read and under- Those who engage in the learning stand. It is the same in telegraphy: process with a carefree, unhurried, how much can we take in and unworried attitude and enjoy it a progress the fastest. So don't "unit?" How big are the units? press your ultimate objectives, This determines how fast we can don't try too hard, this will hinder receive the code. It is the coher- our advancement. Be content to ence of the groupings - what go ahead a step at a time. We need makes sense - which makes for to let go any unconscious resissomething doesn't make sense it scious minds to function without interference. The more we give ourselves permission to let go of any concern and the more fun it is, the better we will do. Someone has written: "When I'm fresh and right on it [which means he is all keyed up and going to try too hard], my code speed is really bad, but when I'm tired I can keep up with the best of them [because he has let go]." (Please review Chapter 2 for details.)

Learning does not stop when a practice period ends - it continues on for a while afterward as the mind continues to digest it, provided that we relax or do somevancement is pretty much up to thing quite different. So space you. So what follows is directed to your practice periods widely you. However, the principles ex- enough apart to give learning a

Kinds Of Practicing

There are several kinds of practicing we can do:-

- Listening practice,
- Copying practice,
- Sending practice, and
- "Mental" practice.

Let's consider each one:--

Listening Practice

Listen, Listen, Listen to well-sent code. *Listen* at every opportunity as well as at planned practice sessions. *Listen* to the radio, to tapes, to computer-generated materials. Do it whenever you don't have something else to do which requires conscious mental activity: try it during lunch, while driving *listen* and enjoy it. There are sevtening at any speed where we can understand all or nearly all of at speeds where we can "read" maybe 75% of it; and finally there is *listening* to sending so fast that we can only catch some letters or a word here and there.

purpose in *listening* at "easy" speeds is two-fold. We want to feel comfortable with the code, just as we normally read and talk without struggling with how we do it. To become comfortable we need to get familiar with the everyday day words and expressions, how they sound. (Engaging in personal QSO's - over the air or through a wire - is one way, and it provides a strong motivation.) We need to feel comfortable, too, at various speeds, from slow to as fast as we can handle it. *Listening* over this range helps gain this familiarity. This is a second goal. But take it easy.

When we let the mind be quiet and just listen to very fast code, Are anticipation and delayed perletters and words will soon begin ception related? We previously Learn to see them on your longer one, until the whole charlimit as to how fast we can spell words.) Give yourself permission tion in the same way. Not jumpto let go of the need to con- ing to a conclusion about what the sciously recognize each letter. faster we can become. That is, let until it is complete before identithe subconscious, automatic mind fying it. Suggested drills are with operate without restraining it by compound words such as "wayconscious interference and con- side, mockingbird, chairman. trol.

eral kinds of listening -- first, lis- Listen at every opportunity to good sending even if it is somewhat too fast for you to get it all. what is sent; next, there is listening Listen. Listen while doing other things that do not require close mental attention. Let your "ears be filled" with good code signals. Don't let yourself get all wound up: keep relaxed. - The Each kind is valuable to us. Our mind is strange - it relaxes when asked to perform at a rate lower than it is used to, but tends to tighten up when asked to perform at a level which it thinks it can't quite hack. The essence of code learning, like language, is familiarity that means over-learning. That is, learning to the point where it is automatic, without thinking about how we are doing it: the dits and dahs, or even the words. The highest skill comes when in reading by ear, we are conscious only of the ideas being expressed, just as if we were talking. This is communicating at the highest level.

Word Recognition Practice

jumping out at us. Want to hear noted that we must not attempt to them. This stimulates the mind. identify a character, particularly a "mental blackboard." (There is a acter has been received. Here we are concerned with word recognitotal word will be when it is a long The less we "try," the better and or compound word but waiting salesman, notebook, lifetime, customhouse, morning-glory hereabouts doorbell, nevertheless

climax, magnificent".

Copying Practice

Copying at easy speeds is of the speed is slower that it actually some, but not great value for im- is. That way he may just go proving speed. To improve we ahead and copy it anyway! must keep working at short bursts of a minute or so at a time, at speeds where we can get maybe only 5Ø - 75% of it - where it is just too fast for us - speeds where we write down what we can get and ignore the rest.

If you don't recognize a sound pattern immediately, just skip it, leave a space and go ahead. -

Never let yourself stop to try to figure it out, because if you do, you will miss what immediately follows. Don't frustrate yourself this way. Keep pressing on, copying what you immediately recognize and ignoring the rest. Remember that here we are only practicing - missing out is no big deal - at this point we're still learning. We must condition ourselves to this. Gradually the holes will fill in and we will be getting it Using a Key To Practice "It is all, and without straining.

Often, even when we're trying to make good copy, missing a letter Most CW operators are more imhere and there won't matter pressed by quality of the code much. If we are interested, the than by speed. gaps can often be filled in later from the context. After reaching a fair speed, it is helpful to copy

watermelon household", etc. and long enough to become tired and words with suffixes such as then still keep on copying. As the "cheerful, personable, fellowship. conscious mind gives up and finality, dictionary, mechanically, stops guessing, this lets the subcharacteristic", etc., or where the conscious mind more and more first part make look like an inde- take over. Then any mental strain pendent word, but with a totally you feel will subside, and you can different meaning as it stands or copy page after page, and yet e.g. "axiom, category, handicap, may hardly be aware of a single sentence in it.

For teachers: Sometimes it may prove best to let the student think

Random character practice at speeds above about 15 - 2Ø wpm is of questionable value unless you are planning to do a lot of copying of enciphered messages. It tends to prevent the development of the important sense of word recognition, something which we must develop for normal use of the code in communication. Practicing with words spelled backwards is a good substitute for random groups: it eliminates anticipation, yet gives give normal letter distribution and the feeling that one is dealing with words, not nonsense. Foreign language texts may also be used profitably, where no special characters used diacritical marks, etc.

Sending Practice

more blessed to send good code than to receive it."

Readability is the number one requirement. It is the sender with hardly surprising, because we al- 2. ready know ahead of time what we are going to send before we send it. However, we may be fooling ourselves unless we have developed accurate sending habits. There is no excuse for sending sloppy CW. When we get in a hurry we may tend to shorten or eliminate spaces between characters in familiar words and between words - this makes it very difficult to read. (When static or interference is present, it is even harder.) If you miss, stay calm, ask for re-And - if we think we can send faster than we can receive it is very often hard stuff to copy.

Remember that What We Do Repeatedly Is Practice, whether we are learning or using code. We need to watch the quality of our sending as we use the code, not to slip into bad habits. Most bad fists have probably come about from imperceptible shifts away from good timing. Avoid the use of buzzers for practice, as they have a delayed start and promote bad sending habits. Use an oscillator instead.

Mental Practice

periods is one of the many valuable means of learning. It is both thinking about the skill you are developing and thinking the skill itself. One way is to think the code to yourself when you see a street sign, car licence plate or other printing. It is even more

his key who has control of this. If effective to whistle it or say it out it isn't intelligible, what's the use loud in rapid dit-dahs. Another of sending it in the first place? valuable form of mental practice Most people consider sending is the picturing of yourself using easier than receiving. This is the code, as described in Chapter

On The Air Practice

"Reality Listening" and "QSO Practice" Don't hesitate after you get your license to go on the air. If you flub up, remember that just about everybody's first few contacts are more or less "failures". Stumble through them, muddle through and make it as easy as you can.

peat if it seems important. If you don't understand some abbreviation or word (he may have spelled it wrong) muddle thru. Laugh off your blunders. Become comfortable about it. You have no job to lose. Listening by pulling weak stations out of interference and static is a skill to be learned. A good IF or audio CW filter will help. If you have one, practice using it. Static crashes which take out pieces of text is another problem: filters can sometimes help, but some have found that by using speeds up to around 2Ø-25 wpm the characters may be squeezed in between crashes, and so less may be lost. This is one Thinking between regular practice incentive for advancing in speed

Chapter 6

How Fast

The Wrong Question.

How Well

"How fast?" - that's really the wrong question when standing all by itself. The question which ought to be asked is "How well?" or perhaps "How effectively?" or "How intelligently"

even then it may hurt rather than to receive. Aim to be one of these. help communication The normal goal is coherency and accuracy. Copyability Speed for us is just convenience.

Commercial operators have al- a highly skilled operator this is ways prided themselves in their almost wholly dependent on the ability to handle a large volume sender's quality of articulation of traffic with dispatch and 100% accuracy. One operator wrote: weighting. One of them said: "I "Over $5\emptyset$ years ago as a trainee can read a super operator at $5\emptyset$ commercial operator I was told wpm, but there are some hams I that it is better to send at 2Ø wpm, and be received 100% the first time, than to send at 28 wpm and be involved in time wasting repeats."

The U.S. Navy insisted on accuracy above everything else: speed

was always secondary. Battles, lives and expensive ships - often the outcome of the battle itself depend upon perfect accuracy in communication. A single erroneous word or number during wartime or emergency might be ruinous and tragic. Accuracy comes first always, at all times there. The telegraph code was devised to communicate - that is its sole purpose.

If the code is not understood it is a waste of time and effort. If we The telegraph code is simply a send personal "dialect" or in a means of communication, and strongly personalized manner we communication is transferring make it hard, or even impossible ideas from one person to another for the receiving operator to make in the form of words and sen- sense out of it. If missed or misunderstood. Mum- there is anything that causes bling is usually inexcusable. downright joy in an amateur's Speed itself is not usually the ob- heart, it is the pleasure of comject, except perhaps in case of municating with an operator who emergency, such as "Help!", and really knows how to send and how

How fast can you copy? Even for his rhythm, spacing and keyer strain to copy at 1Ø wpm - some old timers hard to copy because of bad habits." The key to high speed reception is to recognize the pauses between letters and between words. This means that the sender must not run things

"of" comes when "dahdahdididahdit". We can learn to read that stuff, but when longer and less familiar words are sent and word spaces also are neglected, we can quickly get lost in an maze of letters which make no sense. (It seems to me that as speeds get really high fewer and fewer abbreviations are used.)

Fast Enough To Communicate Satisfyingly

It is possible to creep along at five wpm, the minimum FCC amateur qualifying speed - communicating, but just barely. Many hams in the past found lots of enjoyment plugging along at ten wpm, which for many years was the minimum requirement for an amateur operator's license. Perhaps a majority of hams have found 15 - 18 wpm to be comfortable, adequate and quite pleasant to satisfy their desires to communicate.

graphy sixteen wpm was consid-**ARRL** bulletins have been at 18 ease of operation. (One does not

together. It is this split second it is usually buy a racing car just to the space which gives the time drive to work each day.) On the needed to get the mind set for the other hand, when there is a lot to next word. One of first things say, or when there is a need for that often happens when we try to extensive personal interchange, a send faster is to run the letters and minimum speed of 25 - 3Ø wpm words together. For example, is really needed to keep the out thought moving.

> From listening in the bands it would appear that in the CW mode this speed range seems to be very common. Even when one is contesting, and ragchewing is out of the question, if one moves too slowly, he is going to have a rather low score. But here also, speed, in itself, is not of much value: intelligibility and accuracy are required, and correct call signs, etc., are vital for qualification. There must be a balance.

All through the history of telegraphy, from almost the earliest days to the present, there has been the challenge for speed. The high-speed skilled operators achieved a sort of prestige, which was salable and commercially was rewarded by higher pay. The beginner and the plug were looked down upon with more or less scorn. But as radio amateurs, CW is one element of our hobby, Back in the days of landline tele- something we do because we like to do it. We are subject to neither ered the minimum to qualify a monetary incentive for profinew operator, while 25 - 3Ø was ciency nor threats for mediocrity. considered a "standard" range of It is our own sense of need and speed. For very many years the desire that motivates us. Those among us who can race along at wpm, which is a comfortable buzz-saw rates should not look speed for most of us to read and down upon the rest of us who are copy. It should be clear that content to enjoy lower rates, and speed, in itself, should not be an we slower guys, in turn should not object, but rather proficiency and despise the newcomer, the handicapped or the ham content with thirteen wpm. We don't have to

tracting anything of importance. Amateurs must, however, rememmercial telegrams to reduce the cost.

Various kinds of abbreviations, a sort of shorthand, have been in common use over the years. Many of them were used extensively by people making brief notes, etc., others were devised by old time telegraphers for their special purposes. Several different schemes have been devised to form them:

- Short words may be represented by their first and last letters: e.g. "now" by NW, "would" by WD, "check" by CK, etc.
- Short words may be spelled 'phonetically": e.g. "some" by SUM, "says" by SEZ, "good" by GUD, "because" by BECUZ, etc.
- Other words may simply omit all their vowels and just use the consonants: e.g. "letter" by LTR, "message" by MSG, etc.
- Easily suggested parts of longer words may be represented by a single letter: e.g. in amateur practice "transmitter" may be sent as XMTR, "weather" by WX, "distance" by DX, etc.
- Those who handle considerable message traffic have devised some very brief forms, such as "aa" for "all after".

These were the kinds of things ber the government regulation commonly done in writing com- that we may not use secret codes or ciphers - our communications must be open, which means something generally used and understandable. (The old Phillips code, for example, would qualify because it is public information.) The older handbooks contained lists of the more common abbreviations, a sort of standard list. Some were for general use, others were for handling heavy message traffic, etc.

> When commercial telegraphers were sending press (news) at relatively high speeds they used a very extensive set of abbreviations called the "Phillips code". Here the sending operator translated many of the words and phrases of a news dispatch into this code, and the receiving operator retranslated them back into normal English as he copied the news. This procedure reduced the total number of letters to be sent and received by around 40% (estimated from samples given). When speaking of the speed of press dispatches this factor must be factored in (the counts were based on normal English spelling). Some of the Phillips abbreviations were adopted by amateurs.

> The important thing about using abbreviations is that they must be obvious to the receiving operator. That means they must be common words in normal amateur or everyday use. We must use common sense with them - not overdoing it or using them excessively, just being careful that they will be understood. Refer to

Chapter 27 for examples and lists eating, working with hands on of abbreviations

Chapter 7

Listening or Reading

"Copying in Your Head" Just listening to good code sending is perhaps the very best way, both to learn the code and to advance in skill.

It is surely the simplest and easiest - no distractions - you can give your whole attention to just listening to and trying to understand - no struggling to write at the same time. Isn't that the way we all learned our language? Watch enjoy just listening to good CW. how little children learn.

Listen

some words.

Second, and very important, it helps to reduce any tension associated with getting every letter written down (no distractions) But there is more - it helps us get very familiar with using the code.

So, listen, listen to improve. As soon as you have some masthings that do not require your and over. close attention (e.g., cooking,

routine things). Don't think you need lots of new recordings. Remember that: "To repeat often is to learn." Replaying of the same familiar materials over and over, day after day, is especially helpful if you do it creatively, really listening to it. Play them over and over, paying close attention, trying to understand. As you listen, let your mind be open and receptive - intent on listening to each signal as it arrives. not anticipating or trying to remember what it said before. So. let yourself get familiar with the code by taking some time every day to relax and

This kind of listening is listening creatively, constructively, as it comes along.. This has several Many experienced teachers con-distinct advantages, not the least sider that just listening to good of which is to take away any tencode without writing anything sion or strain - you know what it down is the very best form of is talking about - you are already code practice at all stages. It familiar with it in general and you serves a number of purposes. feel more comfortable with it. First, it keeps our attention to the And - you are getting really fafact that code is sound, and we are miliar with the sound of code - it learning to recognize the sound is becoming increasingly meanpatterns of each character and of ingful to you. So, you can benefit greatly by listening to the same things over and over in this constructive way - just listening as it comes along. But as you advance mix in a patterns of new and unfamiliar recordings, too. The new material will become easier and easier with this kind of practice. You can make your own recordings: -- a few ARRL bulletin tery of the alphabet, start listening broadcasts, quality QSO's - Bible at every opportunity to good passages are good - or other text sending, even while doing other material and play them back over

receiving, when things go very embarrassed (or panic) because slowly, and often again when you you can't read or copy everyhave gained considerable skill, the thing you hear. mind may tend to wander off somewhere else, or go galloping ahead (jumping to conclusions). Am I afraid of losing something? will help us to do that.

We are more likely to rush ahead when we are fresh and alert. Don't let your mind try to outrun the sender. We must resist letting our minds wander off, or anticipate, or pause to try to figure something out. Some of us do this in normal conversation and reading, but we need to be especially on guard against this in code reception. Don't let it become a habit with Morse. As we listen, we need to disconnect all conscious analytical processes, and instead maintain an eager readiness to receive - to hear each letter, word and phrase as it comes along, willing for it to be whatever it will be. That means we hang on to every letter, word and phrase as it comes along, ready for the next one. Listen, keep listening and want to understand. Let's develop Many an old-timer has always the desire and feel for doing this. copied down everything he re-

Especially in the early stages of There is no need ever to become

Whatever You Miss, Let It Go

As you listen, hang onto every I must let go of that fear, and reletter, word and phrase - hang on lax and learn to trust the mind like a leech (that is, concentrate and to enjoy listening. It is a fact on it), really listening to it. (This that the less hard we try, the better also helps; take off any strain, we will receive. Don't ever stop to knowing something of what is try to figure out something you being said.) Remember that in didn't catch. Keep following the practical communications, when sender - keep listening and you we listen to the radio, the signals will soon be getting enough to are here and then gone and can- make sense out of every sentence, not be brought back unless they and in time you will get all of it. were recorded.. You are learning But even when you are quite good to get so familiar with the sound there will be some words which of code that doing it right the first don't make sense at first - in most time will be easy. Easy familiarity cases you will make sense out of it as you go on following the sender, and without even trying. The context and redundancy both help fill in the gaps - just keep focused on the signals. (And don't forget that the sender sometimes may have made a mistake.) If you have learned only to write things down, it will take some practice to learn to "copy in your head" without writing. Listen to understand. Keep listening, not worrying about losing here and there. Soon the signals seem to be slowing down as they parade before your mind or "inner eye" as meaningful words and phrases. Learn to listen for whole words, phrases and the meaning of messages rather than single letters.

Throw Away Your Pencil

ceives: he has never learned to sit whenever there was an opening, back and relax and just enjoy he would send an appropriate conversing. He needs to throw name from his prospect list in listening for listening's sake. answer promptly, he feels tied to his pencil and paper name. This that an interesting way to get a creates a tension, a strain that im- good operator? -- Is he listening, pedes the normal functioning of alert? the telegraphic "habit" of mind. "Throw away your pencil and enjoy just listening" is good advice.

Concentrate

In receiving, we must learn more and more to shut off all distractions and concentrate our attention on the signals we are listening to, what is being said. We need to learn to center our attention consciously on the signals and ignore all else, until it becomes a habit automatic. Prepare yourself to do this immediately before starting to listen and whenever there are lulls. Make it a habitual mental clearing-for-action, so you can pay attention solely to the signals you hear. When we are interested in what we are hearing this will help us concentrate. So let's want to know what is being said - yet not so intensely interested that we begin to guess what is going to be said and miss out on what is actually being transmitted.

An agent who was responsible for hiring ship-board operators was himself a dyed-in-the-wool CW operator. He connected a telegraph key in his office with a buzzer in the waiting room. Then

away his pencil and learn to enjoy Morse code. If the man didn't simply Many a newer-comer likewise skipped him and went to the next

Learn To Hear - Words As Words

Words Are The Building Blocks Of Thought

As you become more familiar with the code alphabet, you will soon be hearing letters easily enough - it is time to begin to think in terms of meaning, that means starting to hear words instead of strings of letters. But as speeds go up, there is a limit to our ability to spell out words. Our next goal is to hear words. Let each word or code group develop on the internal monitor screen of your mind. Begin to develop sound consciousness of words. This does not mean you have to relearn words, but only change your approach from visual to sound. Practicing with lists of words, replaying texts or QSO's this kind of practice can help you gain that familiarity with words commonly used.

There is a limit to our ability to spell words out mentally and remember them. As long as we hear only letter-by-letter, we almost have to copy them down to understand what is being sent. To hear code as we talk, we have to

learn to hear words as words - that mon short words over and over makes the code readable or until they have become indelibly short or long strings of letters. if someone had actually spoken This is stage two. If you have them to you. Extend this to learned to hear and think of at longer words by such methods as least some of the 100 most the following which some people common words as words, you al- have found helpful:ready have taken the first steps. Words are the building blocks of language, so we need to begin to hear, not code or letters, but more and more in words as perception units. (Step three, the expert stage, is to learn to hear more by ideas - total content - than by words.)

How Can We Learn To Do This

Listen For Meaning

When we begin to hear and send in words instead of individual letters our receiving ability and speeds are going to improve. That is part of our goal in making the code more useful and enjoyable. Hearing words instead of strings of letters will make speeding up natural and easy. It will require some practice and effort. The mind has to be pushed, but not too hard. Let's do it the easy way, in short practice periods. Learning to recognize whole words becomes an automatic process of decoding, something that lets us understand as we hear. This is no big job - the word "the", for example, is no longer than the number 9.

Start learning to hear common short words until they have become indelibly fixed in mind as word sounds. Learn to read by words as readily as you recognize letters. First learn to hear com-

"conversational," and not just fixed in mind as word sounds, as

A "Mental Screen" is like a typewriter writing -- visualize a typewriter or blackboard on which writing out each word as it comes, writing it along letter by letter along the line, or like one of those lighted display signs where the words walk slowly across the screen. Let each word develop on the internal monitor screen, or blackboard of your mind so you "see" it being written in context. Try "projecting" the letter or number, etc., for split second on your mental screen as you listen to it to encourage instantly "seeing" it in your mind when you hear it. Learn to write on your mental blackboard. This helps focus our attention on the signals forming words, and learning to "see" them as words. Let you mind be blank as you listen to fast code, and soon the letters jump out at you.

Some have found that "Phonics" can make comprehension and speed building easy and natural this way:--. Relax and think of the sounds of the code letters, not as letter names, but as they are pronounced in words. Like this while the word "west" is being received -- as each letter comes along one after the other say out loud, or to yourself: "wuh, wuh...wee, wee...wes, wes,...west", progressively building up the word in mind by sound. This

sounds. Sound them out one after yourself) as you recognize it. You another as they come along until may want to make up some pracwe get syllables and finally the tice materials which leave wider sound of the whole word itself. It spaces between words to allow teaches the mind to decode the time to say them. (It may also be dit-space-dah patterns and com- useful to practice this way with binations into their sound values, short groups of numbers, such as the way we hear words.

This system doesn't work perfectly, of course, because English is not written in a perfectly phonetic way. Some of the letters are "silent", like final "e." Let the letters combine into words as you hear them in code, much as we recognize words as we hear their sounds You can help by practicing with the common letter combinations (br, gl, ng, etc.) and syllables (com-. ex-, inter-, -ment, -ing, -tion, etc.) to get familiar One ham put it this way: "the stand as meaningful units. It even automatically, now we must take can help with abbreviations. You that next step and trust the same have learned to hear words as demanding to be conscious of the drop-outs while listening.

The importance of **Proper Word** Spacing should become more obvious now. It gives the mind a split second to make sense out of the stimuli it has just received. Those word separating spaces are are long enough), try saying each

makes it easier to hear their word out loud (or mentally to 2 or 3 digits.) Notice how, as you listen, the silence before says "start here" and as the following space says "it is finished", sort of islands of rest. That is why gaining familiarity with the sound of code words is so helpful. It makes the word a meaningful unit, and you get to feeling easy about receiving what makes sense. The more words you are familiar with the easier it is to receive. It banishes tension.

with them. Reading whole words code just flows into my ear and this way then becomes a process comes out as words." Just as we of decoding from something we have learned to let the mind rechear in bits and pieces into ognize each code character and something we hear and under- present it to us consciously and may like to try this approach and mind to store these letters and put let it become automatic. When we them together into words without words, we can often also mentally process and "hear" each letter correct a sender's errors or signal individually. We have to learn to let our subconscious mind present us with the words they form. As long as we insist on recognizing each individual letter, we are interfering, meddling with our normal habitual mind's functioning, and misdirecting our attention.

vital. The following exercise is The goal is to learn to listen to worth a try - as soon as you rec- the code as you would to the spoognize a word by the space which ken word. Eventually the sound follows it (if the sending is not too will trigger your consciousness fast, and the spaces between words just as the spoken word does and also be easier to copy it down.

We Must Listen At Higher **Speeds To Improve**

To improve we must begin by listening at a speed higher than we are comfortable with, in order to get used to it and speed up our recognition. We ought to listen at different speeds, both slower and faster than we can easily read. We need to be flexible - to avoid staying at any one speed too long at a time. Along with this, let's practice listening to lots of standard English at speeds close to our limit. This limit should keep going up as we continue to practice this way. A total of a halfhour a day spent just listening at speeds we can barely follow will work wonders in a couple of weeks. Listen as you would at a Missing Words concert, enjoying it as you go.

Sometimes we should pick speeds Long Words so high that we can only make out a character here and there. This Decapitated Words kind of listening will quickly help us to begin to get more and more. Broken Words Small words will start jumping out - as soon as they have been sent Static, interference or fading can although we didn't consciously spell them out as they were coming in. We need to continue this kind of practice, and soon we will be getting enough of each sentence to make sense out of it. Learning Is Variable Some days don't let this trouble you - that's normal. All of us are like that for a while at each speed.

You will discover that sometimes you can read several words solid,

then, when you can do this, it will and then not be able to read anything more than a letter here and there for some space. All this is part of normal learning. Keep on listening: give the incoming signals your undivided attention and keep relaxed, as though listening to a friend talk. Soon you will be catching not only small words, but longer ones, until you are getting it all. You will discover, with practice, that the signals, which were too fast before, will seem to be slowing down as they parade before your inner eye as meaningful words and phrases. - An interesting example is the blind amateur who could copy 35 wpm, and came across some code practice and listened. He lost a letter here or there, and then was startled when they said it was 55 wpm practice!

we will know what the words are, momentarily wipe out a letter or two, a small word or part of a longer word. Momentary inattention (due to mental fatigue, distraction or something else) on our part while sending or receiving can do this, too. When a word is decapitated the first several letters you'll do better than others, but are missing. This makes things particularly difficult in English, because word beginnings are so important for us to be able to make sense of a word - and worse, this is often the accented part. In fact, when we can get the first sevwhole word is likely to be?

When reception is solid as we are just listening, some strange things along which seems unfamiliar and finally loses the whole word.

How to can we stop this? We mustn't let missing out first part of a word distract us so that we stop hearing the rest of it. - How can we prevent this? Is part of the tension caused by missing out or losing first part due to recognizing a time gap with nothing recognizable to fill it? -- We may be able to recapture long words if we just keep on listening. (When we are copying we can often fill it in First, we must keep focused on the middle of the word. Sometimes automatic mental functioning.

eral letters of a word don't we doesn't make sense, we realize often know pretty well what the something is wrong and wonder what word that last group of letters was. (Let this be a warning to avoid it our own sending.)

may happen: a little word or the When a wrong letter (misfirst part of a long word comes spelling) or a non-character is sent or a word is left out it may has no recognizable shape - and distract us in much the same way. we stumble a moment trying to Really, isn't this much like a mismake sense of it. This tends to print in reading. Don't we often blank our minds against hearing skip right over a misprint or the next few letters and then we missing word and hardly notice are likely to lose the what imme- it? How do we do that? Isn't it diately follows, in the case of a because we understand it in the long word, the whole word. At context? Can't we learn to do this other times our minds sometimes in telegraphy also? -- Where one seem to go into reverse after the or more letters or even words are first few letters of a long word, wrong or missing, can't we often then misses a couple of letters in fill them in correctly? We can the middle, tries to pick them up, learn to do this for missing or extra dits, etc., mentally correcting them as we listen. As we have emphasized before we must just let it go and keep on listening. If we pause try to figure it out at this point, it will divert our attention from reception to analysis, and seriously disrupt with our automatic reception as we try to make sense out of it. Frequently we discover that as we go it will clear itself up.

afterwards from the context.) A incoming signals without strugbroken word (interrupted, dis- gling to make sense out of them. jointed) results when the missing Trying to make sense is a conletter (or letters) occurs in the scious activity, interfering with the this break is due to the sender sense of concern is involved who inadvertently hesitates an in- concern that we won't be able to stant too long between two letters. remember the first part until the In either case, the space between word is finished, or that its beginletters is too wide and our minds ning is peculiar, has no recognizinterpret this as a break, marking able shape (e.g. technical or it as the end of one word and the medical terms), or that it is going beginning of the next. Since it to be a word we won't be able to

familiar). For many words, one not identical, can help us separate way to help is to get familiar with them, while the speed and style of the common prefixes and suffixes sending also help greatly to sepaso that they are "heard" as units rate the one we want from the instead of separate letters. We other. In addition, the ear can be must learn not to let conscious trained to read incredibly weak thought block further reception.

On-The-Air Listening

When we listen on the radio, static, fading and interference tend to Some have found that by listening audio filters, changing the tuning of IF amplifiers, etc.. These will help separate signals and reduce noise.

Static and irregular non-signal types of electric interference can often be reduced by turning down RF gain and increasing AF gain to bring the signal up. Some noises can be canceled in the brain by using headphones wired so that they are out of phase with each other. Dual-diversity reception can greatly reduce or eliminate fading, but this requires a major equipment change: two separate antennas and two identical RF front ends are necessary. The ear is an excellent discriminator of CW signals in QRM, noise and other interference, much superior to any equipment available today.

We can train our ears to minimize interference by focusing our atto hear. The musical pitch and

slow us down. Under these condi- in the dark, or closing their eyes, tions high quality sending (accu- they can focus more sharply on rate timing) will get through far signals which are in the midst of better than sloppy sending. But interference and other distracthere are certain adjustments or tions. You may want to try it and changes which can be made in see if it helps you develop or imour receiving equipment which prove this skill. Finally, sometimes will help: e.g. the use of RF and writing it - copying - may help us to concentrate.

> Any experienced telegrapher, regardless of what he is doing effortlessly hears what is being said on the air or on the wires

Chapter 8

Copying Getting it written down

This is really an extension of Chapter 7 To the principles given there add these: -- If you are going the easy way, copying is the next step after "listening" -- advancing in code skill by adding the new action of writing it down.

What we hear as letters and words are now to be written with pencil and paper or with typewriter. It is learning to co-ordinate ear-tomind-to-hand. Copying by hand tention to the one signal we want exposes all the senses to what you are hearing, and it is nothing

more than listening to and writing so well that it has become second down what is being received. An natural for them. old 1854 book on telegraphy described it as "taking dictation" at first letter-by-letter, later as word-by-word, etc. That is a good way to think of it. So, hunt up that pencil again. Operating ability is measured by copying: if you don't write it down - putting down everything you hear exactly as you hear it - you aren't copying.

A skilled operator is trained to way, wondering why he was using copy what he hears $1\emptyset\emptyset\%$ per- voice to send these simple data. fect. Most people can learn to Voice? What voice? copy with a pencil up to about 25 sending clear code with letterwpm (a few can reach 35, rarely number combinations at 25 wpm 45), but above that speed almost and I was copying it easily." Aha! everybody needs a typewriter The listener was now thinking in also be done "mechanically" by as code characters at all. He had direct ear-to-typewriter-key trans- become proficient. fer without processing it through the letter stage to the typewriter key. - See later in chapter) Remember - don't try to do more than one new thing at a time. You already know how to write. When you copy by hand, make it easy by writing the way you usually do. For example, don't try to block print unless this is natural and easy. Likewise, don't try to copy on a typewriter ("mill") before you have learned how to As in listening, this helps by distouch-type.

While most of us would like to know what we are copying as we copy, this isn't necessary. It can become so automatic that we copy something correctly without realizing what we are copying. (I usually like to know what I am copying, don't you?) People who do these things well do not struggle with them - they have learned

Here is an interesting example of copying properly:- One night, as I was copying mixed groups in a very relaxed manner, and feeling quite comfortable with the code, I asked my friend if he would speed up to 25 wpm from the 2Ø wpm he had been sending. He started sending them at 25 wpm, and I was vexed at his misunderstanding, but began to copy any-He was ("mill"). (On a typewriter it may terms of letters and numbers, not

> To copy just Write Down what you hear, everything you hear not what you think your hear and you will make progress. The faculties of hearing and understanding code signals work best in learning to coordinate this way to create a useful copying ability.

Practice With Familiar Text Helps

pelling the fear of missing something, because we already know what it is about. By using things which we have read, or recorded material we are already familiar with, we feel more comfortable. When we know, at least in general, what it's about or what it says, we know what to expect and not worry about not understanding and losing out. It helps build con-

hind. The more familiar we are interesting as possible. with what we are copying, the easier it all becomes. This confidence will begin to carry over into receiving new and unfamiliar materials also.

Pay No Attention To Any Errors

comes easily. As you practice, good in the early stages to make copy everything you instantly recognize and pay no attention to acters correctly and to prevent any errors -- just forget them and anticipation, but because it is go on.

If You Miss Anything Just Go

Let it go, forget it and keep going on. Train yourself to leave a blank space and go on, because if you stop for even an instant to puzzle over a signal you didn't recognize, you will miss at least some of what follows. We must condition ourselves to do this. After all, we're learning.

The holes in your copy will gradually fill up and you will be keeping relaxed while you go, just leaving blanks for each missed letter or word. (However, characters we habitually miss do point out what needs more practice.) sometimes mis-hear, or misidentify a character or a word the sender may have made a mistake. -- Count these things as of no importance, and keep at it until you can do it easily. Don 't work so long at a time during these learning stages that you get tired or bored. Use a wide variety of

fidence in learning to copy be- material and choose it to be as

One student, speaking of ARRL practice materials, said: "I made more progress in learning code in weeks than I did in years previously, because it is more interesting to copy and understand solid copy." Some practice copying Condition yourself to copy what random 5-character groups is sure we are recognizing the charmeaningless it soon tends to become boring. -- Too much of this may also lead the mind to expect a break after each five letters when we are trying to copy normal English. This has happened! (Practice with "Backward English" - provided in some computer programs - is better because the letter groups are of variable length and have normal letter distribution.)

If You Want To Become More **Proficient**

Who Doesn't? If you are able to copy every letter, you are not learning - but if you are only getting two letters out of every three, or four out of every five, your Remember also that we may mind will be motivated to get that extra letter. There is always some speed at which for the time being and also it is always possible that each of us falls apart - so what? It need not become a barrier. you want to become more proficient, don't practice at such a slow speed that it becomes a fixed habit.

> Keep trying in short bursts of not over a minute or two at a time at higher speeds 2 - 5 (or more)

mind to respond faster - it will. This is especially important when we are at a speed where we getting about 95% of it, so that we don't become satisfied to stay there. It is often best to begin a practice period, when the mind is fresh, at ognizing some characters quickly a speed too fast to get more than about half of it, and then slow down. - Keep moving up faster to improve, because then copying at a little slower speed than your maximum will become easy and enjoyable. Alternating with some practice at 2, 5 or more wpm above your limit for brief periods will challenge the mind, then dropping back a little will show vou are really improving. Every the next one arrives. It is worse operator soon develops enough when two E's, or EI, IE, TT or awareness of what he is writing other short letters occur together, down, that he doesn't need to wonder whether it is copied correctly.

In The Beginning

If you begin copying early, you will be copying letter-by-letter, sticking close behind the sender: you hear the character and write it down, then forget it and listen to the next and write it down, and so on. But to copy this way for very long, in step with each letter being sent, tends to tense us up. It becomes tedious and tiring because it is meaningless and so much conscious effort is involved. Then copying we may lose out.) In practicing to speed up copying, try not to stop if you fall behind, just keep going.

wpm faster in order to force the The beginner is afraid of losing something, because he can't get it all down fast enough. He is frantically struggling to keep up, "tail-gating" the incoming signals, so as not to lose any of them. This is because he is still not recenough. The problem is made worse because the characters are received at very unequal rates of speed as compared to writing them down. The letters "E," "I" and "T", for example, are the shortest letters, while C, J, Q and Y are the longest ones. A beginner copying letter-by-letter can get panicky trying to write down an "E" or other short letter before and we frantically try to write them down before the next one comes along. As we advance most people can copy letter-by-letter up to about 25 wpm or even faster, but above that we simply have to find a better way.

A Better Way

Copying Behind

The first step to making copying easy is to learn to copy behind. That means training the mind to act as a buffer, or short-term memory, between hearing the incoming signals and what we are you usually have to read what you writing down. Several characters have written in order to under- or words are automatically held in stand it. (If we look back while mind after hearing them and before writing them down, meanwhile continuing to listen to the next ones coming along. This helps smooth out the uneven rate at which characters are received as

compared to writing them down, it, keeping the spacing between and also it relieves the mental groups wider than normal. Listen strain of copying. It serves as a until both characters have been cushion. In this way we can also heard before starting to write make much better looking copy them down. As this becomes easnames as we hear them.

Copying behind is another good way to beat anticipation. It puts a premium on listening before you write A good operator seldom starts writing a word down until it is completed. By starting out using things which we have read, or recorded material we are already familiar with, we feel more comfortable. When we know what it's about or what it says, we know what to expect and not worry about losing out.

Above about 25 wpm, we need to build up vocabulary of at least the most common words and syllables. Practice waiting until a syllable or short word is finished before starting to write it down, then try it for two syllables. Writing down more than that behind what has been sent may be risky - the word may turnout to be longer unexpected letters may still be coming and surprise you, making you miss them or even more (If you're still going at 4Ø wpm you will have to copy word by word.) Some people seem to develop this ability without any special effort as they progress. But for most of all without some help.

How can we learn to copy behind? Is there something we can do specifically? There certainly is. Here is one way to begin: start out with random two-character groups at first, until you get the hang of

and can even capitalize proper ier, try groups of three, then of four and if you wish up to five or more. Practice also with decreasing spacing between groups until it is normal. Another approach with any kind of text, is this way: listen to the first character, but wait until the next one has been completed before writing the first one down; write down the second one after hearing the third one, etc. Then increase the number of intermediate characters between hearing and writing to two, then three, etc., as far as you wish.

> This kind of practice should be extended to include short syllables and short words (such as the 100 most common words), in each case waiting until the whole syllable or word is completed before starting to write it down, and while listening to what follows. To extend this to more than a couple of syllables or short words can be risky, because, as noted before, something unexpected may come along and throw you off balance, and cause you to miss some of what follows.

An interesting example is this comment (from the time when a government inspector had to test us it just doesn't seem to come at each individual applicant for an operator's license):- "I can remember the benefits of copying behind. The inspector giving the test started and sent 'of' and then added an 'f.' I immediately thought of 'off' and got set for the next word, but to my dismay, without a pause he sent an 'i' and

so immediately I tried to outfox him by prewriting the word 'office' To my consternation he kept We can hold in mind only a few on going with 'cia' and I quickly revised my thinking to 'official.' But I was wrong, because he finally ended up with the word 'officially.' Listening first and copying behind are beneficial." So, copying a word or two behind is a leisurely pace, but too much more may produce some mental strain, especially if an unusual word comes along.

in sending. Context can help. (Numbers, however, have no context and generally must be copied without delay.) The purpose of copying behind is to relieve the mind of the compulsive pressure, the strain, of keeping up letter by letter.

Most high speed operators who experts, such as Ted McElroy seem to have been able to copy 6 or more words - even whole sentences - behind with no trouble at all, but most of us probably cannot.) Copying letter-by-letter forces one to write with conscious effort, and this in turn blocks our attempts to copy behind.

What Makes Sense Is Easier

individual numbers or random characters at a time because they usually have no coherence, no meaning - they don't make sense as syllables and words do. Words and phrases are much easier to remember than a string of letters or numbers (or a call sign) because they form meaningful groups, not a lot of little unrelated pieces. This is why Walter Can-Copying behind has many ad- dler, who in earlier days taught vantages besides making it easy. many operators to become ex-It allows us to make a neat, fin- perts, was convinced that learning ished-looking copy with a proper to hear words as words was essenappearance, capitalization and tial for efficient copying behind. punctuation. When it is at speeds (He was a strong proponent of well below our limit, it gives us listening practice.) We can learn time to fill in gaps and flaws due to copy by words as readily as by to static, etc., and to correct errors letters. For example, the word "the" takes no longer time than the number "9."

Copying behind by syllables, words and even by longer expressions is merely an extension of this. If we build up our working vocabulary (word-familiarity) as already discussed in Chapter 7, "Listening", this will help us a have discussed this subject tell us great deal. As speeds go up you that we need not copy more than will find that, by around 400 wpm one or two syllables or words be- you're copying word by word hind, and in fact as speeds go up and by 6Ø wpm (if you go that this is about the safe limit. (Some far) it will be more like copying phrase by phrase.

> Old time telegraphers used to say that their "alphabet" was words. That is, they had a wide working vocabulary of words that they instantly recognized when they heard them. When they heard a word coming in on the line in code, they heard the word, not the

some proper name or something tinuing to go ahead - including unusual that they had to spell out. more practice on the sticky char-They had a familiarity with words. That is why one of them, who also was a well-known teacher of Morse code, said that by listening and re-listening over and over again to the same recorded code tapes of regular English text, this will help us to become intimately familiar with the words - that is, over-learning. We need to get familiar with words as they sound in code.

Conquering Our Fears Of Losing Out

Law 3 if you miss something: condition yourself to skip it. Keep copying everything you recognize instantly and easily and shrug off the holes left over. You'll soon be surprised to find the holes gradually filling up. If you are frightened you lose much of your ability to copy code well and - surprisingly - your sending speed also tends to go up (as much as 25%). The parts of brain that copy normally are pretty much shut down.

At first it may not be easy to let go, and allow some characters or words, which we can't quite consciously identify, pass by. That doesn't mean we stop listening or paying attention: it means we are learning to trust the mind to store them safely in its immediate, retrievable memory and not get panicky or confused because we are not conscious that they are there. So, especially in practice, if you miss a few letters or a word here or there, don't worry.

individual letters, unless it was Overcome this fear by just conacters - and you will surprise yourself to find you will recall them. Because our fear of losing out is the greatest barrier to copying behind, Candler devised some special exercises to help us get started with a minimum of strain. It goes like this:-- take a list of short words in two parallel columns, preferably words with about the same number of letters each, and:-

- With pencil or typewriter write down the first word in the first column while simultaneously spelling out loud the parallel word in the second column, and so on down the columns. (We may do it again, reversing the column order.) Try it with 2-letter words first, then longer words till you get the knack of it. - As a useful variation, try sending the one word with your key while spelling the other out loud.
- Have someone "read" easy b. printed matter to you by spelling out each word at a regular, even rate of speed and a level tone of voice. Don't begin writing the first word until the third starts, and keep on two words behind, and then if you wish, with three words behind, etc.

Finally you may repeat it using code instead of voice spelling. Do these exercises slowly enough that you don't feel rushed or have any fear of losing out. Don't do it beautiful longhand up to 3Ø - 35 too long at a time: a couple min- wpm - solid deliverable copy, utes at a time are enough to get while a real good operator using a the hang of it.

Other Suggestions

Finger Writing

Try some "copying" this way:-sit as though were going to write, using your index finger instead of a pencil (or your hand as though you held a pencil), letting it rest lightly on paper while listening to the code. You may try it as motionless copying, not moving your "copying inhead"only, or you may prefer to "write" with your finger. Either way, it can help wean us away from that baby step of letter-byletter copying, and graduate us into seeing several letters or words as a unit in the mind's eye.

Once we've gotten the knack of it, ters. Under these conditions one we will discover that visualizing can copy page after page and not and holding the letters, even for be aware of a single sentence in it. just an instant, will help us to copy better and faster than the old onthe-edge way - almost a reflex or Poor Fists action. All this is training the mind to dig up the images of words that have already been sent. It will develop a sort of automatic response: ears, mind, hand all coordinating together. Remember: to ignore any errors, not to work too long at a time, and - don't forget: you're just practicing. So give yourself a chance. In learning to copy on typewriter, go slowly at first. You may find it easier to use either caps or lower case altogether at first. Until the typewriter became practical old time Morse telegraphers copied all messages with pen and ink in

mill later could take 5Ø -6Ø wpm without overextending himself. Most copied 5 - 6 words behind to do this. (OT bulletin Jn 92 p

How Long Shall I Practice

Until you have gained considerable skill in copying, avoid working too long at a time. but after this point it is good to practice copying for longer periods without fatigue. When you have reached a fair speed, long copying practice can be helpful because by the time we are getting somewhat tired, our subconscious mind is translating the dits and dahs so that we do not feel that terrific mental strain that is the cause of guessing at certain let-

Fading, Static, Interference and

In the old days when all ships used spark only it took a lot of concentration and skill to copy a station a thousand miles away when another ship 15Ø miles away was transmitting. When there were static crashes it was hard (and they also often sounded like parts of code letters). Learning to copy a weak station thru static and interference and fading is an art in itself, and to master it takes quite a bit of practice. It taxes the skill of the operator to the utmost, as it is often necessary to retune the receiver and go back and fill

a signal that can hardly be read. ing, poor rhythm or Signal fading is something to weighting. contend with, but during practice even that may prove to be a bene- Correcting Imperfect Copy fit to us. Copy what you do hear and leave a space for what you can't. It can help us learn to ignore lost sounds.

kept right on copying when most as we are learning. us wouldn't even have heard the signal at all. Their jobs depended Other Observations on it. That is skill, and CW does get through. Some hams have learned to do this just as skillfully -- they have learned to copy signals against intolerable background noise, noise to signal ratios of 1Ø dB or more.

It takes practice and patience to learn to hear the weak stations under the loud ones, but we can learn to copy a weak station buried under several strong ones. This is a truly remarkable ability of the human operator: to read of strong distractions. It does take A skilled operator who can copy came quite proficient. solid at 5Ø wpm with good qual-

Examining our pracence and fading so bad that others tice copy in this way can also be a had to ask for repeats, and they valuable tool, and encouragement

At the expert stage where copying is automatic, the most common copying error is said to be getting so personally interested in what is being received that we begin to anticipate what is coming next, and then if it turns out to be something unexpected, we may lose out something. Learning to copy on the "mill" (typewriter) without knowing what is being copied was actually used during WW2 in Africa, when operators were in short supply. Native Afriincredibly weak signals in the face cans who knew no English at all, were taught to associate each code concentration, and the advancing signal with its corresponding operator should be developing typewriter key. They quickly some of it. Bum "fists", bad learned to hear the character and sending, is something else again. punch the proper keys, and be-

We should learn to send so distract, have sometimes been clearly and accurately that the found useful to relieve the tedium receiving operator gets perfect for high-speed operators making copy every time. (Most of the difficulty in reading and copying code is due to irregularities in spacing between letters and words. See Chapter 15 Timing.)

"Over 5Ø years ago as a trainee" said one commercial operator, "I was told that it is better to send at go he and how been into great 200 wpm, and be received 1000%

Rule Two:

Never send faster than you can receive properly

Break either rule, and you may end up sending poorly formed characters or a choppy, jerky style that is hard to copy, and establish a habit that will be very difficult to overcome later. Bad sending is not cured by changing keys, but by correcting wrong mental impressions.

Keying And What It Means

The genius of the Morse code lies in its simple modulation requirements - only two "states" needed: Ø and 1 (binary code). These two states may be any sort of distinct differences in condition or quality of the modulation: ON\OFF, and for electrical and audio signals may include pitch and quality, as well. This greatly simplifies the equipment required for transmission and reception. Any form of two-position switch which can be operated at a satisfactory rate of speed by a human operator or mechanical or electrical device will serve the purpose. For electrical and radio telegraphic communication the switch may simply control the "on" and "off" conditions (single-polesingle-throw switch).

This opens a wide range of possibilities for mechanical designs, the simplest being just touching two wires together and separating them (which has served in emergencies), to electronic "switches" their conductivity between very teachers today recommend that, if

high and low values by electronic means. For code transmission we generally call such switches "keys", "keyers", or "keying devices". In this chapter we are primarily concerned with hand keying, that is, using the simple up-and-down hand key "straight key". (See Chapter 1Ø for other types and their use.)

The First Morse Key

Alfred Vail designed the first "straight" key and called it a "correspondent". It consisted of a board on which was mounted a simple flat metal strap spring attached to the board at one end and on the other end having a small knob on its top side and an electrical contact on its bottom side. This contact was arranged so that when the knob was depressed it would make connection with a second contact mounted directly below it on the board, thus permitting the closing and opening of a circuit. When the pressure was released the spring caused the circuit to open again. It had no stops or adjustments of any kind.

This "classic" pattern of up-anddown movement has governed the design of all "standard" keys ever since.. Later models have simply been "improvements", variations and elaborations of this basic concept.

Recommendations To The Beginner

Sending with any kind of handoperated key is an art that takes which have no mechanically some time and practice to develop moving parts, but rather control properly. For this reason some

possible, the beginner start out sending preferably with a keyboard (or code-programmed computer). With a keyboard it is impossible to send poorly-formed characters. A keyboard is a typewriter-like device which produces the code character corresponding to the key pressed. There is no way you can misform a character with a keyboard - you can only push the wrong button. (See Chapter 1Ø.)

A keyer (see Chapter 1Ø) always produces perfectly timed signal hand control should avoid the use elements and inter-element spac- of any hand keys, at least while control the sequence of the spac- skill.) ing of letters and words. This requires considerable skill and may discourage the beginner. It is easy to send well-formed characters, but unintended or even nonexistent ones may also be created. Therefore it seems wisest to begin learning to send with either a straight key or a keyboard. (A straight key does help to reinforce the rhythm patterns of the characters more effectively.) In any event, it is well for the beginner to heed the advice of a wise teacher who said:- "Do not touch a handkey at any time until I tell you that you may."

This advice has a two-fold purpose:

- 1. To make sure that the student has an accurate mental impression of the correct sound and rhythm of the code characters before trying to send them, and
- listening to one's own poor sending may actually hin-

der learning (as noted in Chapter 3).

So the best way is not to touch a key until you have developed a good feel for the proper rhythm of the letters. This usually means by the time you can receive at about 1Ø -12 wpm or more. When you begin with a straight key you must have a good feel for timing - that is, the three building blocks of code: the dit, the dah and the several lengths of spaces. (Those who have poor ings. However, the operator must they are gaining in receiving

> After you have learned the proper rhythms, sending with a straightkey, whether for practice or in actual use, sending with it is quite beneficial for building up your receiving ability in all its aspects. In addition it develops muscular memories which further strengthen our perception and recognition of characters and words. Constant practice in sending this way does help build our copying ability. Sending practice also prepares the hand and arm for transmitting over long periods of time without fatigue. Finger and arm exercises may also be devised to help gain needed flexibility and strength.

The Straight Key

A standard "straight" key is one having a simple up-and-down movement. In American usage the key should be aligned so that key lever is in a straight line with the forearm. To control it, the operator moves the knob by a pivoting

hand and arm muscles do not fa- (The student should find his own vor the very small movements most comfortable way.) Downneeded to control key motion.) ward movement of the knob to The design of a key, its location close the key and upward moveon the operating table and ma- ment to open it are by rocking the nipulation tend to vary from hand, pivoting it from the wrist: country to country, and its ad- the finger end moving down while justments in the final analysis de- the wrist moves slightly upward, pend almost entirely on the refer- and vice-versa, without any acences of the individual operator, companying independent finger Here we can only give the gener- motion. The upward key knob alities and some instructions by movement is produced by the experienced users.

The American Straight Key And Its Use

The key lever is generally relatively thin and typically pivoted so that its front section is longer than the back section, and often droops downward toward the knob end. Its control knob is flat on top and may have an underskirt (originally designed to protect the operator from high voltages on the key lever). The top of _ the knob should be about 1-1/2 to 2 inches above the table, and have firm adjustments for up-anddown movement (nominally about 1/16 inch movement at the knob, but adjusted to whatever suits the operator best).

The key should be located far enough back from the edge of the operating table (about 18 inches) that the elbow is just off the edge of the table. The operator's arm rests lightly on the table with his wrist off the table and more or less "flat". His first finger rests on the top of the key knob and his second finger generally on top near the edge. His thumb may rest lightly against the other edge of

up-and-down wrist motion. (The the knob, or not touch it at all. built-in spring in the key, but may be helped by the thumb.

> Walter Candler's advice to professional telegraphers in training (to avoid developing a painful "glass arm") was:-

- Hold the knob between the thumb and first two fingers much as you would hold a pencil. Hold it firmly, but do not squeeze it or let go of it while sending.
- The wrist not the fingers or the whole arm - does the work as the key goes down and up. Keep the wrist off the table.
 - Take care of the sending arm - the forearm muscle carries the weight of the arm. Otherwise, keep the arm itself relaxed and at ease as you move the key down and up. - Immediately below the elbow on the lower side of the arm there is a nerve which comes close to the surface. If that nerve presses against the table it may begin to make the arm cramp and produce telegrapher's paralysis ("glass arm"or

writer's cramp). If this happens, put a soft pad under it there to relieve this condition.

- There is no need to waste energy on springs. The key return spring does not need to be stiff - just enough to keep the contacts apart.
- Contacts should be spaced only wide enough apart to be easily opened and closed. A key is obviously a highly personal object. Every one who has gotten his own key adjusted till it feels just right will be uncomfortable and fail to send as well if he uses a different key, even though it looks exactly like his own. If you set up two different keys of identical design, with the same tension, and gaps, they will nevertheless "feel" different. They are as individual as violins.

Gaining Skill, Errors, and Automaticity

needed to send accurately. This in a formal message. turn produces strain, and soon

one finds he working against himself, and (with a straight key) if he sends for long periods of time this may develop into "glass arm". (See Walter Candler's advice) The master operator does not send a single needless dit or dah.

What About Mistakes Made During Sending? If you make a mistake while sending, just correct it, if necessary, then forget it and calmly continue on. Don't let yourself get all tensed up and start to worry about making more mistakes (such as: "Now I mustn't do that again!"). If this keeps bothering you, focus your attention for a just few moments on sending each word (or maybe even each letter) as it comes along, sending evenly and with proper spacing, and then go on normally as if nothing happened. This will help create a positive, constructive attitude rather than a negative one. As for correcting mistakes, general practice varies: eight dits (like HH sent without space between the letters) is the official standard, but it is more common to use the question mark For the skilled telegrapher the and then send the word (or with characters and words flow without the preceding word also) again conscious thought as to their de- correctly. Personal Characteristics, Fists

Chapter 9

All sending with any kind of a Sending and the Straight hand key will show little personal Key - Part II quirks, or characteristics collectively called one's "fist", which KEYS unconsciously develop as one's skill and experience grows, no matter how precise an operator may try to be. This is why a receiving operator may immediately recognize a sender and say: "I know that fist," even before he identifies himself.. Our fist may also betray our mood or state of mind - excitement, fatigue, boredom or laziness - much as our tone of voice often does.

Someone said of one operator: "his code almost seems to yawn". But there is more to it than that. The type of hand-key being used which may also affect the sending. This does not mean that high quality code cannot be made on any of these types of keys, but rather that their particular construction and use tend to produce certain characteristics.

With a straight key, side-swiper or bug it is easy to send a jerky or "choppy" sort of code, as well as to make inconsistently longer or shorter dits or dahs overall or in certain characters. A common fault with using a bug is to make the dits too fast as compared with the dahs. Side-swipers tend to encharacters, inconsistent formations. The type of key in use may greatly influence one's fist as it sounds to the receiving operator

The design of the key and where it is placed on the operating table are important for comfort and ease of operation. The height of the knob or paddle or its feel may not feel quite right, or the key movement may be too much or too little, or be too stiff or too soft. (One British examiner said of candidates coming for their sending test: "It never ceases to amaze examiners that some candidates come for a Morse test without one [their own].

Attempting to send perfect Morse on a strange key is an obstacle that candidates should never burden themselves with on the day of the test.") -- How does this key "feel"? Could I enjoy using it? One skilled operator said: "When using a new key, for a few weeks all is well, and I love it. Then, suddenly, I hate it. Then I try another, yes, the cycle repeats itself! Why do I feel this way?" -- It is not hard to see why some commercial operators always took their keys home with them or locked them up! Nor is it surprising that the absolutely inviolable rule of the old time telegraph ofcourage to some very oddly timed fice was: Never, never, never, under any circumstances whatever, touch the adjustments of another man's key.

> Not only the key itself, but the height of the table on which it rests can also be an important factor. Some have, often out of

matter of what we are used to.

The Traditional British Key And Its Usage

The first impression of this type of key to an American is the massive ruggedness of its key lever and the height of its control knob. These notable features derive from a late 19th century Government Post Office design (they operated the telegraphs). Its key lever is a straight and heavylooking brass bar pivoted somewhat toward the rear of the midpoint. The major part of the weight of the lever works against the return spring. Its control knob is smoothly contoured and generally resembles a wooden drawerpull, somewhat pear-shaped, or crank-handle shaped, usually with a distinctly rounded top surface. Its diameter swells from its base to a maximum somewhat below the top. Its maximum diameter is similar to or may be somewhat greater than the typical American key knob. All versions are taller than the typical American knob.

The net effect of its straight lever and taller knob means that in controlling this key it is not suitable for any part of the arm to rest on the operating table. Therefore it is typically mounted so that its knob is close to the edge of the table, with the arm extending out fairly high in front of the table.

As the years have gone by there have been many variations of this it with the whole hand. Again,

sheer necessity, used a key type of key, different spring armounted on their leg, on a handle, rangements, different dimension etc. Cramped and awkward oper- ratios, different knob contours, ating positions have often been bearing supports, etc., but the necessary. And then there is the heavy style lever and high knob have remained as more or less permanent characteristics.

> The traditional way of using this type of key is:

- to hold the key knob with the first finger on top, the thumb underneath maximum diameter on the one side, and the third finger on the opposite side from the thumb;
- the operator's lower arm extends outward approximately in line with the key lever (horizontally and vertically), unsupported by the table, several inches from the side of the body, and forming an angle of approximately 9Ø degrees relative to the upper arm;
- the main keying movement is at the wrist, not at the fingertips, with the wrist acting as a hinge between the arm and the hand.

The hand, wrist and arm are not strained or rigid, in spite of the seemingly awkward appearance of such an operator's arm position to us in America. Beginners usually adjust the key for a large gap so as to hear the sound of the key closing and opening. They generally reduce this gap as their speed increases (some reduce it to the barest minimum). Some operators control the knob delicately with their fingertips, while others grip help open the key by their wrist ing-practice periods. movement; others rely entirely on the spring return action.

As the beginners progress, they headphones: one phone carries adapt their keying style to what- the recorded code signals, while ever is comfortable to them indi- the other phone lets the student vidually. Australians have said they found it very hard to send properly with the American keys - with their flat topped key- Most teachers recommend beginknobs, located far back from the ning with relatively slow hand edge of the table - as installed in movements. About 12 conair-ground-air stations during sciously controlled hand movesance!" In summary, with all is the often-repeated reversals these variations in basic and detail which limit performance. Total design, it seems obvious that there reaction time from external inmust be more than one way to struction until the hand reacts is design a good key and use it.

Using A Straight Key

It is, of course, impossible to send absolutely perfect code with any purely manual device, but we should learn to imitate perfect sending as best we can. If you have an instructor, he should demonstrate quality sending for you to imitate something like this, for example: "Listen as I send the character..., and then you say its just like you hear it." This is repeated several times until the teacher is satisfied, and so on

some operators prefer very light throughout the alphabet and spring force and use the thumb to numbers during the early send-

> Another way, which can be used without a teacher, is to use split

> There is at least one computer teaching program (see below) which has an option which will evaluate the learner's sending.

WW-II. They called these keying ments per second is average, but arrangements "a flaming nui- some people cannot exceed 1\,\Omega\$. It about 15Ø-2ØØ milliseconds (ear- or eye-brain-muscle). Responses must be much faster than this for sending code, playing the piano, etc. This is where the automatic mental functions take over.

A good beginning practice with a straight key is to make a string of dits at a slow, even rate for a minute or two, and then gradually to speed up to a comfortable rate. Then send a series of 2Ø - 3Ø S's name as you send it back to me evenly and smoothly, with proper spaces between them. After that, send a corresponding string of dahs, followed by 2Ø or more O's the same way. This will develop a

proper feel and a sense of control of the key. After that, try a short sentence in a slow and uniform way, with wide spaces between letters and words, something like:

I Always Send Evenly And Smoothly

Try this several times, gradually shortening the spaces until they are about normal. Listen as you send it for accuracy of timing. Try recording it so you can listen later to it without distraction and evaluate how it sounds to others.

With a clear, easy and correct style of sending it will take about ten minutes to get warmed up, and from then on you should be able to send for a long time without the slightest discomfort. A reasonably good operator can learn to send good quality International Morse on a straight key up to 2Ø - 25 wpm. Some can make 3Ø wpm, but 35 wpm seems to be about the absolute limit (equivalent to about 45 wpm for American Morse). On the other hand, don't assume that just because you can receive at say 25 wpm you can send well at that speed. -What isn't intelligible isn't worth sending.

Glass Arm

Candler's description of Telegrapher's "Glass arm," or "telegra-All these may be prevented or pher's paralysis," is:

relieved by proper mental and

A progressive and painful forearm condition where the arm gradually loses its former snap and responsiveness, and the dits become difficult to send correctly at one's cus-

tomary speeds due to partial loss of control.

Fatigue sets in early and sending becomes "rotten", leading to discouragement or distressing irritation. It may or may not begin with a sensitiveness, which soon subsides, but true glass arm has neither inflammation nor soreness. This condition is caused by needless strain or tension or poor key handling, and is avoidable. Factors which may lead to it are:

- _ Poor posture,
- Holding the arm in an unnatural or uncomfortable position, so that blood circulation and nerve functioning are interfered with, making the hand uncomfortable, cold or clammy,
- Undue pressure of the underarm on the table,
- Unduly long periods of sending, confinement or lowered body tone which induce muscle strain and tension,
- Conscious interference with normal automatic habitual control, or
- Even the suggestion that by prolonged use the arm will ultimately fail.

All these may be prevented or relieved by proper mental and physical corrections. Some have found relief by rotating the key to use a sideways movement. Others cured it by going to a side-swiper, or more often by going to a "bug". Candler said that a false glass arm may occur when some infection is present which pro-

back and neck and/or headaches. ening, as I found that after a Its cure is obvious.

Tests for Proper Operation of a **Hand-Key**

For the beginner everything will be easier if any serious faults are caught early, before they become habits. There are two general kinds of tests for an operator's sending ability. One concerns the quality of his sending, its readability, and the other concerns his An excellent test for endurance endurance and comfort. Quality and comfort is to sit down and of sending may be evaluated in send straight reading matter at a several ways. It is a good idea to comfortable speed of from say 15 record some of your own sending - 25 wpm for about an hour. It occasionally and let it sit a day or will take about ten minutes to get so and then to listen and see what the fist limbered up, and if one it sounds like - is it easily read- has cultivated that clear, easy and able? A rougher way is to gage by correct style of sending that is so the comments of receiving op-desirable, from then on one can erators (or by the number of send for a long period of time times a repeat is requested). This without experiencing the slightest is strongly suggested also for bug discomfort. On the other hand, if operators.

There are several computer programs to evaluate one's sending against the ideal. One of the excellent ones is Gary Bold's diagnostic program, DK.BAS, designed for this purpose, which runs under QBASIC, a part of his Morse teaching software. (See What Is It That Makes a Good Chapter 18) Looking at your own sending may be very humbling, but this program will show exactly Ease of operation and positive improve it.

A typical comment of those using it is: -- "My sending can't really be that badly, can it?" But after taking DK.BAS's advice, the same operator said: "Actually the

duces pain in the wrist, forearm, whole episode was quite enlightnumber of attempts I had improved to the extent that I and the computer parted company on speaking terms at least". If you are sure there's something wrong, but can't quite put your finger on it, let such a program find it for you. Your sending will really sound better if you concentrate on making the improvements indicated.

> the fundamental principles of correct key manipulation have not been learned, one may just 'blow up' after the first 15 minutes with a hand too jerky, and a wrist too sore to want to go on. That says, take a look for what you're doing wrong.

Hand-Key

what's wrong, and tell what you control are prime considerations exactly what you need to do to for any hand operated key. The first Morse key (called "correspondent") was designed just to the minimum needed to do the job. Later designs took into account other factors as well, including ease of use and appear-

ance. In the early days of high Is this telling us that it isn't the powered wireless (spark) stations design of a key per se that makes function again took over and it "feel right", but rather that it is these keys were awkward, massive what we are familiar with and are things in order to handle the huge used to? It feels comfortable currents involved.

freely without detectable friction, and at the knob or paddle there or small keys have not been should be no perceptible move- popular, although sometimes necment in any direction except that essary. What a key is mounted for normal keying. The return upon - a wooden table, one's leg, spring should be adjustable for best control (some recommend 25Ø - 4ØØ grams pressure range for a straight key). This spring should not be so stiff that sending is choppy, or so weak that signals tend to run together, but always factors that are partly hardware, adequate to open the circuit by partly psychological and quite itself without assistance from the personal. operator.

For a given rate of keying, the force required is a function of the spring, gap setting and the inertia of the moving parts. The key lever should be stiff enough to give a firm contact without noticeable vibration or bounce (no double contact). Bearings should be solid at all times. (Firm electrical contact is best made with a flexible wire rather than depending on the bearing points.) The return spring should have adequate adjustment range to satisfy operator preferences. Gap setting should give a firm feel and have a wide enough adjustment range for personal comfort. Is there a key is design that universally "ideal"? -- My impression is that well-accepted keys show a wide variety of design details to meet preferences.

partly due to national- historical A good key lever should pivot and partly personal preferences. For some unknown reason, short a concrete block, etc. - and how it is mounted can make a great deal of difference in how it feels. It may feel "great" or "responsive" or "dead" or have disturbing vibrations. These are all

Chapter 10

Other Keying Devices And Their Use

In Chapter 9 the regular "straight" keys were discussed at length. Here we look at all keying devices.

These may be classified as:

- Keys (including "straight" keys, "side-swipers", and semi- automatic keys or "bugs"),
- Keyers (keys and keyers may be called "handkeys"). and
- Keyboards (including computers programmed to send like a keyboard).

All Kinds of Keys

Innumerable variations of simple mechanical switches may be devised. Almost any conceivable kind of motion may be used to operate the switch: up and down, sidewise, sliding, squeezing, twisting, etc. They may be actuated by: human action (finger, hand, arm, foot, lips, neck, breath pressure, etc.), mechanical or electromagnetic action (e.g., in a relay, to duplicate the keying patterns in a second circuit), etc.

For the handicapped several kinds of keys have been devised to be operated by breath pressure on a diaphragm or piston, etc. Some of the interesting recent designs take advantage of solid-state circuitry using such things as a) the interruption of a light beam by a finger tapping in front of a photosensitive cell, b) the change of capacitance or resistance produced by moving a finger to approach or lightly touch a fixed metal pad, c) the tone of a human voice humming in Morse code within the range of a tiny microphone, and other possible means to control the keying. How does one classify such devices?

Other Kinds Of Manual Keys

The Double Speed Key or Side-Swiper

After the "original" Vibroplex speed key was introduced in 19Ø4 it soon began to be widely used by commercial telegraphers used it found its sidewise movements much more comfortable as much an attraction as its claim and natural, and also that it pre-

vented or reduced the risk of glass arm. However, it was rather expensive. This idea of easier and possibly faster sidewise movement later led to the simpler, so-called "double-speed" key (also called "side-swiper", or "cootie key"). The paddle of its key-lever closed the circuit whether moved to the right or to the left. It sidewise movement offered relief to operators who had suffered from 'glass arm". (A few operators, following this idea, simply turned their straight key around 9Ø degrees so it could be used with a one-way sidewise motion.)

In use the operator formed the code characters by using his thumb and forefinger to press the paddle alternately from one side to the other as he formed the successive dits and dahs for each character. For example, if he typically made the first element of a character to the left (L), whether it was a dit or a dah, its next element was made to the right ®, and so on, so that his pattern of movement was L-R-L-R-L-R . . . or R-L-R-L-R-L . . . This back and forth motion often tends to lead to a sort of peculiar rhythm of its own, betraying that a "sideswiper" is being used.

Commercially made double-speed keys were relatively cheap compared to the Vibroplex, and it was quite easy to make a good homemade one. No wonder that it became popular in wireless operations, especially among hams, for some years. (It does not seem to (see "Bug" below). Those who have been used by landline telegraphers.) Perhaps its novelty was fatigue.

Of passing interest in 1926 was a On the Australian land-lines bugsimilarly connected key having keys were known as "jiggers' two pushbuttons, like typewriter Those issued by the Sydney GPO keys or pushbuttons, to be used Telegraph Office in 1946 had 3 with two fingers, called the knobs, two of them controlled "Cricket" by its manufacturer, separate swinging arms, one for The keys were to be used alter- automatically forming dits and nately to form the characters, as one for automatic dahs and the with the "side-swiper". sending, radio requires a heavier He cites a common technique for heavier key will help do this. So or interference.

Setting the Adjustments of a Bug

Like all keys, bug adjustments are a highly personal matter, varying from one operator to another. They are also sensitive to the range of speed. For example, a bug set for 35 wpm operation will do poorly at 18, and vice-versa. --Remember the rule: NEVER readjust another operator's bug!

Hugh S. Pettis, K3EC, recommends the following as optimum bug settings:

- It is to be understood that operator's personal comfort and ease of operation govern the details of setting the adjustments.
- First, set the adjustments for paddle displacement so that it moves a comfortable and equal amount for dits and
- Set the spring tensions for comfort of paddle opera-
- Set the movable weight on vibrating arm for the speed desired.
- Dit weighting is determined by the distance of the stationary dit post from the contact on the vibrating arm.

style to put the signal through setting correct dit duration (a dit static and interference, and a equals unit space) is to clip an ohmmeter across the bug termibe sure to set heavy enough dits nals. First, set it for full scale while that they are not likely to be holding the paddle against the swallowed up by moderate static dah contact. Then adjust the stationary dit post contact until it gives a mid-scale reading for a series of dits, and finally settles on a full scale reading - a closed circuit. His personal preference is for the dits to taper off to a closed circuit after about ten dits. More dits will give a lighter weighting, and if the series leaves the circuit open, it is too light. Fewer dits will produce a heavier weighting, and if it is fewer than eight, the nominal (8 dit) error signal cannot be made.

> Robert. R Hall W9CRO recommends: (Some adjustments are interactive.)

- Adjust top and bottom pivot bearings so contacts are all on same level, just tight enough so that side play is barely perceptible.
- Set the armature (the movable part controlled by the key tabs) stops:--
 - Adjust the dah stop screw so the armature just touches the damper when held against this stop. (Damper contact should not be more than just enough to stop the swing.)
 - Adjust the dit stop screws so that end of the armature will oscillate when it is moved

against this stop with a brisk paddle movement of about 1/8 inch.

- The tension of the armature return spring should not be heavy, but just enough to return the armature to the right hand stop screw without any bounce, and without any tendency to bounce off the damper.
- _ Set the "dit" action very carefully:--
 - Set armature weight(s) about _ of the way to the slowest speed. Then.
 - Push the armature paddle to the dit position and hold it there until motion stops, and continue holding it there while adjusting the contact screw so that it just makes firm contact (but not so light that it arcs or misses). Some previous adjustments may need correction now.
- Set the dah action:
 - Set the contact adjusting screw (which is also the stop) so the paddle moves about 1/8 inch.
 - _ Its spring should be set to give about the same paddle pressure as for dits.

Sending With A Bug

Key smoothly and easily with a minimum of effort. Let the bug do the work - you just control it, with the arm resting on the table, touching the paddles loosely (lightly) between thumb and fore-finger. Control it without much motion of the hand or fingers. A slight twist or roll of the wrist will change from the dit to the dah side. Relax and enjoy it. Don't bat out the dits and dahs out with thumb and forefinger so widely separated and so hard that it tends to push bug around.

There is a marked tendency among some bug users to set the dits too fast relative to the handformed dahs and spaces. Handformed spaces tend to become too long in proportion. The result is often a choppy sounding code or to signals which are certainly readable, but tiring to listen to and read. Katashi Nose KH6IJ points out that "at high speed one cannot put much force on the paddles." He also said that "If you move your whole arm, the law of inertia prevents you from attaining high speeds."

Keyers

Keyers are electronic devices controlled by paddles similar to those on a "bug" for automatically making dits and dahs, and often incorporate other useful operating features, including buffers and memories. Many include "iambic" type of operation by a "squeezing" motion which provides for alternate dits and dahs, which further automates

sending and in this way reduces Psychological testing shows the total effort. An iambic keyer will always produce perfect characters, even though they may not be used in our code.

Katashi Nose here says "If you have already mastered a bug, it will take about three weeks to convert to electronic-key sending. On the Low side: 6.7 per second, Once you are converted, you are hooked because now your bug fist is ruined [ed. for most people]; an entirely different technique is required." If your keyer has "forced character spacing" (FCS), use it! This may take several weeks practice, but your sending will be real armchair copy. It is worth the effort.

Keyboards

Finally, the keyboard (including the use of electronic computers with programs for using their keyboards) automatically makes all characters from a typewriter type of keyboard. Both keyers and keyboards often include teaching programs for learning the code and/or improving code abilities, as well as having memories for various purposes. This is about the ultimate in code production. (Machine sent CW is considered almost a "must" for good copy when signals are very faint, including QRP - and for very high speed work (hand sending just won't hack that.)

Keyboards also have much to offer the beginner in learning the Average for five-letter word = code initially and for improving one's skills. What may be possible hand-key speeds?

average rates at which people can tap a fingers:-

On the High side: 9.7 per second, or 576/minute, (3ØØ in 31 sec)

Average: 8.6 per second, or 516/min. (3ØØ in 35 sec.)

or 4Ø2/min. (3ØØ in 45 sec.)

If we assume that a dit is one "tap" and a dah is equal to two "taps" (two nerve pulses: one down and one up), then we may say:

Taps	Letters	Group Freq	Taps x Freq
1	Е	Ø.13Ø	Ø.13Ø
2	ΤI	Ø.166	Ø.332
3	ANS	Ø.214	Ø.642
4	DHM RU	Ø.192	Ø.768
5	BFG KLV W	Ø.124	Ø.62Ø
6	C O P X Z	Ø.139	Ø.834
7	JQY	Ø.Ø24	Ø.168
Average per let- ter		1.ØØØ	3.494

17.47 taps.

At this rate, assuming the above rates can be maintained for periods of time needed to send messages, news, etc., the slowest keyaverage 3Ø and the highest 33 wpm.

An Interesting Bug

The Sydney Australia GPO Telegraph Office in 1946 produced a bug that had two separate swinging arms for dots and dashes. There were 3 knobs: one for dits, one for automatic dahs

and one for manually controlled dashes. The knobs could be positioned at either end of the baseplate for easy use by right or left handed people

Chapter 11

Further Development of Skills

Recognition of CW is a process of learning to perceive intermittent sounds as intelligible "speech."

Real skill begins when we no longer think of the code as code, but only of the content. A good operator is one who feels quite at home with code, fluent in it. He is able to copy accurately up from a low of about 15 up to about 25 wpm and can think and talk in telegraphic words, almost as if it were ordinary language at speeds sometimes up to 3Ø-35 wpm ("conversational CW" as one teacher happily called "rag chewing").

This ought to be the minimum ambition of every operator, because it makes the game all the more enjoyable, a very comfortable working range. He enjoys it

ing rate would be 23 wpm, the and feels no strain or pressure. He is competent. (Anybody can talk into a mike.) By omitting needless words and with the help of common abbreviations, Q signals, etc., his rate of communication is high enough to be comfortable, and he feels no particular drawbacks when he talks in Morse code. Sure, he may spell or sound out unusual or strange words or proper names, just as he would when he meets them in reading or writing, but mostly he hears words as words because he has become more proficient. Words are the "alphabet" of the skilled operator.

Higher Skills

As we talk about these highly proficient men and women, we must draw a distinction between reading code at these speeds and copying it. All through the history of telegraphy skilled operators have said they could "read a whole lot faster than they can copy the stuff down." Obviously no one can copy faster than he can write - whether by hand or on a typewriter.

We have already discussed copying. In this chapter we address reading skills again. We're talking here primarily about amateurs who have achieved a still higher degree of skill, not for commercial or professional reasons, but simply because they want to. It may be for sheer enjoyment or to satisfy an inner drive, but whatever may be the reason, such an ability is as worthy an objective as any other skill, and even more so, for it is useful as well as enjoybe enough.

Doesn't our satisfaction over managing to get even one recognizable word out of a high speed code transmission trigger a desire to be able to read it all at that speed? "The joys of high speed to doubt - he knows he can read it give further help, making CW needs to.

The following is an interesting example: On a local SSB net of high speed operators the controller asked: "Gary, can you operate SSB as well?" After a short pause, somebody said: "Gary, He's talking to you on SSB!" "Ah" said Kirby, "So he is!" --!Morse is so much a second nature for There are said to be four phases those with real skill that they have of skill: to stop and think what mode they're actually using. It will surprise you when you first experience it.

Truly High-Speed CW Awaited Electronics

High speed CW demands precision: it did not become a reality for most operators until digital communication in the form of

able. We need incentive - motiva- microprocessor controlled keytion - to achieve, and that ought to boards became available. This made available at reasonable cost the two parameters which are paramount to enjoyable highspeed CW operation: -- accuracy, which is always the most important and never to be sacrificed for speed, and speed.

CW are known only to those will- An operator cannot send accuing to put forth the time to learn rately enough with a mechanical what a unique world exists on our device at speeds much over 4Ø bands." This semi- pro is com- wpm for any length of time, but a pletely relaxed as he effortlessly keyboard makes that easy. In adreads or copies: he has no reason dition, its features of memory, etc. even while doing something else. communication better, with the Regardless of what he may be result that operators can now condoing, a skilled telegrapher hears verse instead of carrying on what is being said in code within monologues. The human mind his hearing. He reads it like he manifestly is better equipped than hears the spoken word and may any computer to copy the Morse even be able to remember it later code, and the joy of operating well enough to copy it down if he comes from listening to accurate CW send by a skilled operator. No matter what sending device is used. The point is to send Accurately. It is the mind that copies CW, and it is in the head that pleasure is found.

Looking Backward And Forward

- Hustling for the letters,
- Learning to hear words,
- Taking in several words, a phrase or short sentence at an "ear-full", and finally
 - The real expert who has the details of Morse code so well in mind that he gives them practically no atten-

tion at all, and only is conscious of the content.

Remember that in the earliest stage we learn to hear the letters as units of sound, rather than hearing the dits and dahs as such. Next, we advance to hearing many common words and parts of words as units, instead of strings of letters spelled out. At this point we are quite conscious that the dits and dahs are there, and this gives us a sort of inner confidence that the foundation is in place (our security blanket). Up to this point we feel comfortable.

The third step comes as we pass the point of being able to hear the dit and dah components any longer - they seem to have vanished into a blur. (We should still be conscious that the letters are present, however.) At first one may feel somewhat helpless, as though the supports had somehow gotten lost. However, the automatic mind, which has been trained by enough of the right kind of practice (and has been active all the time, though we may have been unaware of how far its activity extends), seems to be able to hear those components and identify the letters with no strain. What we must now learn to do is to **Trust** this mental ability although we are unaware of how it works.

"Conscious effort is fatal to speed"is a common observation with respect to any skill we have acquired. "The moment you let yourself think and cease to rely on 'instinct' you will fail in these special skills." If a code transmission is played at 2Ø wpm for the

rank beginner, his probable reaction will be: "I will never be able to read or copy that!" However, after as few weeks of training he will be doing it. High speed code may seem far too fast ever to read, but it is not nearly as fast as it sounds to the uneducated ear. A good share of the problem is overcoming the impression that it might not be possible to comprehend at such a speed. One stubborn fact faces us: others can do it, and surely I can, too. Therefore, take heart. We recognize that it is hard to understand recorded speech when it is played back at twice or at half speed because not only the pitches but the sounds become so distorted.

This is not true of code, where the important proportions are strictly maintained the patterns are still there. Skilled operators need to learn to read and copy over a fairly wide range of speeds. Ted McElroy once said: "If you can pick out even one single character at a higher speed you are on your way." So if you have ambition, take heart! When the mind is near its limit, struggling, concentrating on each individual letter as it is heard, there is no time to identify letters poorly sent, jammed together or missed, or words misspelled, etc. But if we have a comfortable margin of speed, this makes everything easier and much more enjoyable.

At slower speeds we can then reason out the words because we have time to think over each word as it comes in (we can't change the sending operator!). Early in the day we are likely to try too hard. Especially when we are

your interference". We must stop sionals, but now many are hams this internal warfare, this conscious attempt to control reception. Make it let go let go, so the unconscious inner mind may function. Give yourself permission to let go of your conscious demand to recognize each letter. The better you succeed and the less you try, the better and faster you'll become at it.

As one student said: "When I'm fresh and 100% alert, my code strongly when I asked him one speed is really bad, but when I'm day after a QSO: "What word was really tired I can keep up with it that W8xxx used to express . . best of them." Does that give us a .? -- He didn't know. There was hint as to how to go about it? an expert.) (This is not speaking of the beginning student, who needs to put his whole conscious attention on learning the sound-letters, but to the person aiming for very high speed reception.)

The Skilled Operator

A long-time telegrapher was once given the code test at 13 wpm for a General Class ham examination, lost much below about 12 wpm

> One old timer, now a silent key, who had begun as an amateur, then for an interim period of time was a commercial operator and could copy 4Ø-45 wpm with no trouble, and could easily read up into the 5Ø wpm region, said that as a ham he always listened for ideas, for meaning, for sense, and was hardly conscious of the actual words sent. (This came out

Above that speed is the super expert who lives in that upper atmosphere where 6Ø wpm is loafing, and some have been able to comprehend at 1ØØ wpm to as high as 125 wpm (one of these was the well-known Bill Eitel of the Eitel-McCullough Co., tube designers and manufacturers). Some of these whizz-bangs tell us that they don't think there is any but laid down his pencil and said: real upper limit in speed at all. "I can't copy that stuff." When Like most of us at such speeds, asked why, he said: "Well, it's just probably none of them contoo slow." Everybody laughed, sciously hears more than a buzz. then they speeded it up consid- (He wouldn't even think of trying erably and he made perfect copy. to listen for the dits and dahs.) What are these race-track opera-The expert, who is a step up, races tors doing so differently from most of us? -- They are hearing in

contests)

Somewhere above about 45 wpm speeds become too fast for us to be conscious of the difference between dits and dahs. The facts are that at these higher speeds unless we have actual hearing defects - the interior workings of our brain are quite aware of these differences and can discern the patterns accurately, and so can convey to us the bigger picture of words and meaning, but for some reason will not allow us to be consciously aware of the details. The experiences of the operators described here are evidence of this.

Reading Versus Copying Skill

Many highly-skilled longtime landline and radio telegraph operators are said to have copied at steady rates between 5Ø and 6Ø wpm all day long for a 1Ø - 12 hour day. This was common on where." That judge had passed press circuits, as well as some others. (However, there are some questions - we may suspect that they were typing $5\vec{Q} - 6\vec{Q}$ wpm in actual word counts, while receiving in Phillips code, an abbreviation system which typically shortens the number of letters by about 4Ø% [See Chapter 27.] If so, this would be slower actual code speeds than in full normal English at the given speed.)

At high speeds, over about 45 -

longer spans than we are. Their copying - but not reading "groups" or units of comprehen- quickly becomes very exhausting, sion are longer than ours, and and can be continued only for they are not consciously thinking very short periods of time. For of code characters, letters or them as speeds go up, getting it probably even in words as such. from the ear to paper demands (See below and Chapter 26 Speed the utmost of concentration, shutting everything else out of mind. Some have described it as almost being hypnotized. (In great contrast to "comfortable" speeds of 2Ø to around 4Ø wpm, depending on one's degree of skill.) Tiny lapses of attention for them can be devastating. Since we have already discussed copying (Chapter 8), our attention here will be confined to reading the code

The Sound Barrier

Sound Consciousness - From Details To Meaning

After an official amateur speed contest about sixty years ago, one of the judges, himself a former telegrapher, asked the young man who won at 56 wpm: "Listen, Kid, did you get it?" - "Sure, why?" -"Well, all I could hear was just one endless string of dits without even so much as a space anyhis limit.

"Sound consciousness" has been used to denote the limit beyond which a given person can no longer consciously distinguish the components of the code. At speeds somewhere around 5Ø wpm it becomes impossible to make out the separate dits and dahs any more - they become a blur. Conscious recognition of details ceases, and if one is to continue reading the code signals, 5Ø wpm, many experts agree that there must be a distinct change in

the consciousness of reception. already moving forward." Sound consciousness must shift !Listen, listen, listen and want to gears from letters to words and understand what you hear. Rephrases.

This ability is developed by allowing the automatic mental functions to completely take over the recognition of all details below word level, without any conscious interference whatever, so that from then on one is conscious only of words, phrases and meaning. One has to let go of any demand to be conscious of the details.

How Can Such Skill Be Developed

One man did it this way:-- when he got so he could copy 14 wpm almost solid, he tried a 21 wpm tape speed and was surprised to be able to get about 60% right off. After three 15 minute sessions, one a day, he was getting 4 - 5 words or groups in a row without misses. He alternated back and forth between the two tapes, and found it helped both. Continuing with still higher speed tapes, he was able in about 5 months to copy at 35 wpm. (Many have gotten to that speed much sooner.) So, try listening at speeds 1Ø or more wpm above your present limit, and as you listen see if you can hear anything recognizable. Want to understand what you hear.

A number of the very high speed start hearing short words, then more information on this point.) you're on the right track, and are

member the rules for practicing work in short enough bursts of speed so as not to get tired, then drop back to a slower speed again and it will seem much easier. One of these experts says that he feels comfortable and does not sense any degree of tension or strain at all while reading or copying at these very high speeds. Nor does he sense any changes in mental action or approach as he listens at any speed. He says that at these high speeds he is not conscious of dits and dahs, and only sometimes is conscious of the letters, spelling, etc. ("You don't even need correct spelling at these levels.")

Unusual words, a proper name, call sign, abbreviation, etc., do not "throw" him and so he doesn't miss anything following it. He adds: "The faster the code speed, the better." (As for copying at very high speeds he says: "I usually listen for the first sentence and then start to copy.") In these comments he is joined by another expert. Both of them were initiated into the code before the age of six by expert close-relatives or friends. They feel entirely comfortable with code at any speed, and feel that there is no upper limit in speed. "The one thing that myself and others [find limiting] at high speed is the matter of putting QSO's on paper. operators have said that if you can Copying is the only limit." (Is catch just one word in a high beginning at such an early age speed transmission, you are on part of the reason they feel so your way to reading it. "If you "comfortable?" We need some

this skill as something like this: - denly becomes intelligible. Snap-"You mention [hearing only] a ping into high speed code may be 'blur of sound' at higher speeds. something like that. This happens to me too, where the Ted McElroy and Levon R. code [at first] sounds like popcorn popping or chicken grease on a hot griddle, and I have to concentrate to 'break the sound barrier' before it starts making sense and I can read it. ... I have to make my mind break into this and begin concentrating on words and phrases.... [then suddenly] one word or phrase snaps me into gear and I go on from there. Then so long as I consciously maintain my concentration, I can continue to read it in my head ... without much sense of strain... [Then] so long as concentration is strictly maintained, 'drop-outs' [from this receptive state of mind] do not occur.'

He admits that he misses occasionally - a hard or unusual word really wants to." or a misspelling, etc., but he just continues on - there is no time to ponder about it. This indicates that he senses the need for some the following thought:other. If your attention is on the (as to the press in former ears). newspaper, you are usually be aware of the radio only as more or less jibberish, a noise. Then, if you want to listen to the radio you have to turn your attention to it,

Another of these experts describes and what was jibberish now sud-

McDonald were men who before WW2 demonstrated copying in the 75 wpm range. A few years later Frank J. Elliott and James Ralph Graham demonstrated the same degree of expertise. There were others who were runners up. McElroy said there were many others who were as good as he was, or even better, who never entered the speed contests. George Hart said:" If you were born with a whistle and no voice box, you'd be able to send and receive 1ØØ wpm or more. I guarantee it! It's all a matter of incentive." "Sit and listen, and keep listening and want to understand it." "Anyone who can type over 75 wpm can copy code over 75 wpm if he

This handicapped teen can "copy" at almost any speed with Some Outstanding Examples Of 1ØØ% accuracy, but he doesn't really know a dit from a dah. He didn't learn the code this way. Code was always the easy part for him. Rob is certain that anyone who can't pass the code exam must be an idiot, since it wasn't very hard for him and he has a learning disability, cerebral palsy which restricts his coordination. He had Steve's excellent example and was never told it might be "hard", so it was always easy for him. He had a good attitude and didn't know there was any probhis ability. He was learning it the right way from the very first exposure.

More Examples

The U.S. Navy during WW-2 code courses for the average person required about 3 weeks to achieve 12-14 wpm to meet the rigid It was his conditioning, his back-Navy requirement of perfect acbetter teaching methods.

Waldo T. Boyd K6DZY was a graduate of the Navy Radio Communications School. In 3 months time he was copying 35 wpm, and not long after that was copying 5Ø wpm easily. Dick

before his 13th birthday he did Spenceley KV4AA known as "one of the world's best operaearned his license and was working DX at 2Ø wpm. his was the result of a good teacher and an eager student.

Effectiveness

Conditioning Is Important

Katashi Nose KH6IJ (Physics Department, University of Hawaii), who became a high speed expert, taught teenagers the code for 25 years. His students never heard that "this will be hard, you'll or you'll have to fight a plateau." They learned rapidly to good working speeds of 2Ø - 3Ø wpm in two to three weeks.

The fastest code learner we have lem. There seems to be no limit to ever heard of so far started code practice for the examination just one week before he took the test and passed it! You say: "Wait a minute. What goes on here?" You're right, there is a history behind this achievement. What was it, and what can we learn from it?

ground. That played a crucial curacy (military operations and part. His father was a skilled telesecurity at sea demanded letter- grapher at a country railroad staperfect accuracy). This time, they tion. His earliest childhood thought, could be shortened with memories were of sitting, fascinated, on the floor in his father's telegraph office listening to the sounder clicking. Unconsciously he learned to recognize when his Dad's station was being called, and when he did, he would go to get his Dad. It was only after he

was quite a bit older that he realized that not all adult men could automatically read Morse code in the same way that they could read and write English!

His mind had become so sensitized to the sound of Morse code from birth and so saturated with it it properly, he had absolutely no cess. hang-ups at all about "not being able to do it". He was totally conditioned and prepared. And in addition he may have felt, as almost every teenager does, that "whatever Dad can do, I can do better". Not many of us are so fortunate as to have this kind of background, but does his history suggest anything we could do? Is there some way I can condition my mind to make it easier? Isn't it the old story: what is familiar to us doesn't seem hard - it is easy.

Gary Bold, ZL1AN, well-known teacher in New Zealand, related this story of a friend of his, and suggests one way to approach it that works, even though it may sound silly. This is by playing high quality code tapes in the the dishes, cleaning the car, etc. work? It's certainly worth a try.

At the lowest skill levels: fouryears-olds, barely able to write even block letters have been able to pass the code test. How many of us are willing to admit a fouryear-old can outperform us? Then consider these higher skill levels:

Determination and Persistence

How long it should take depends on various factors. The first essential is how we approach - this is vital. Am I prepared? Do I really want to learn? Will I stick to it? Am I determined to do it? All that, when the time came to learn these are essential to rapid suc-

By Contrast

Old American Morse operators, using the old visual, then widely practiced methods of teaching and experience, took about six months to reach about 15 wpm and about two years to reach an expert phase. Their code with its internal spaces does require more timing sense than International Morse.

During WW-I in America, the urgent need for wireless operators shoved most of them out the door into military service with only a bare code proficiency, no experience in operating either the equipment or the procedures.

WW-II American military radio background (like music) while training schools provided more you're driving to work, washing rigorous code training, and some of them included, in their later You don't even have to listen to it phases, operational experience consciously, he says. - Will it with wired QSO's and even included interference. These practical exercises sometimes introduced progressively worse QRM. Some courses introduced typing from the very first, but for advanced students typing was the rule. Those receiving high speed training also learned to copy high speed press. It is easy, and need not!take long to learn the Morse code if one goes at it prepared

Chapter 13

The Role of Memory in Telegraphy

Why Learning Initially by Sight Doesn't Work Well

If you "memorized the code" (as I did) from a printed chart of dots and dashes, or from a clever knew the code.

ceive, to listen to the code, that the mechanisms. To fill in the picture, trouble began. The sounds you experimental studies on memory heard just didn't seem to match have for many years shown that up with the dots and dashes you we have not only several kinds, "knew" at all. Why should it be but also several levels of memoso hard to translate the code ries. First are what may be called sounds into the dots and dashes the "sensory registers", the very and letters that you thought you short times during which, after we made a study of memory tell us sound persists in our consciousthat we have several separate ness as if we were still seeing or memory banks: one for sight, one hearing it (persistence of vision or for sound, others for touch, taste hearing) for a moment, then and smell. (See, e.g., "Memory: quickly vanishes. However, if we Surprising New Insights Into How We Remember and Why We Forget" - Elizabeth Loftus, 198Ø)

Now we see why: the code sounds we heard couldn't make any direct connection at all with our

with the right attitudes and meth- vivid visual memory: they were two different kinds of sensations (sound and sight) -- they didn't relate. In order to cross that gap and relate them we had to give conscious thought to build a bridge between them: to convert the sound pattern into a pattern of visual dots and dashes so that our visual memory, where the "memory" was, could interpret them. That is why we stumbled and, under the pressure of time, often printed diagram or picture which missed out or even failed comvividly impressed the mind, you pletely. If we keep on this way we felt you knew it. Maybe it only will have to form additional assotook you twenty minutes to ciation links for each individual "memorize" it, as some advertis- code character in order to connect ers claimed - or perhaps it took a them. This can be done, and has day or two. Then if you!tried to been done, but it takes a lot of send something in code with your time and also raises a new risk key, it was easy: you had a vivid the danger of interference bemental picture as to just how long tween them (two possible pathto hold each element of a charac- ways, one conscious, the other the ter, and this seemed to prove you new association formed) and possible hesitation as a result.

But it was when you started to re- Our memories are complex knew so well? Those who have see or hear something, its sight or are paying attention and are conscious of a sight or sound, it will enter the appropriate "short-term memory" and stay there for maybe 15-2Ø seconds before it, too, fades out unless we deliberately try to remember it a bit the process of copying, the conlonger, lor make a real effort to sciousness of content may be put it into our "long-term mem-zero: you just mechanically copy ory" bank by intending to re- (dictation) what is received, while member it (by reinforcing it).

Long term memory is what we usually think of as our "memory." Because for most of us it seems easier to remember things we have seen than things we have heard, the visual approach to learning seems more attractive. But obviously, since receiving the code is a matter of hearing, we should begin the right way, by training our auditory memory banks. Now we can see why learning the code initially by eye is really the hard way, and actually creates a serious roadblock to advancement.

Some Further Questions and Thoughts

The intricate inter-working of the various parts of our minds and brains raises questions as to what is going on as we consider receiving in the telegraphic codes. Memory studies are usually concerned with things we are fully conscious of and desire either to remember or to forget. With the higher skills in code, however, it is the operation of the unconscious parts of the mind and its relations with the consciousness that is of primary interest, and how these tie together with the memory.

As our telegraphic skill level increases, the ABC's of the mechanics of language become more and more the actions of the subconscious mind, which in turn may or may not bring them to the attention of our consciousness. In

you may be conscious only of thinking of something quite irrelevant. However, in reading the code we are first conscious of the words, and later conscious more of the thoughts conveyed than being precisely aware of the words. In both these higher skill levels, the words and thoughts are generally collected together into at least the "short-term" memories, and often carried over into the "long-term memories," so that we "make sense" out of it all and follow what is being said as we do in conversation.

Perhaps the only thing we are conscious of, if we stop to think about it at all, is that we want to understand and recall some of the things said to us. Perhaps there is an analogy with driving a car. Here our eyes are receiving impressions from traffic, traffic signals, certain sounds, and our physical responses on steering wheel, accelerator, brakes are so automatic that if we are asked later about some particular detail, we just can't reply. These habitual physical responses to stimuli from specific events are especially strongly retained over long periods of time. The complete response once started carries itself out automatically and fully.

Another, less frequent occurrence is this: over the years it has been found that people sometimes have retained mental "pictures" or "sound recordings" of things in earlier life to which they had paid no attention or had any interest

were able to recall them - even full context, not in sequential things that!made no sense at the time. One operator accustomed to time or later. One aged lady was operating in the 35-4Ø wpm able to recall verbatim long range was out of it for five years. speeches (in a language foreign to When he sat down to listen he her) she had heard many years could copy only about 15 wpm: previously. Another sang a song "I couldn't believe it!" Just a few perts tell us that "long term hours of practice were needed. memory" does not mean either "One can indeed get awfully permanent memory or accurate rusty," he said memory. All memories tend to weaken or fade out with time, and further, that they can and usually are altered in various ways so that the recall is distorted, or sometimes even reversed from the original.

One exception is those memories associated with physically-related skills, such as playing a musical instrument, driving a vehicle, stenography, telegraphy, etc. People who have not practiced such skills for many years will generally show surprising agility after decades of non-use. A little practice will usually put them back to nearly their best performance, barring physical disability. This has been demonstrated over and over. There is certainly room here for further research into this fascinating subject as we look for specifically better ways to improve our telegraphic skills.

Those operators in commercial work who read the tapes by eye seldom if ever learned CW as we know it, but rather learned the visual appearance of words and letters on the tapes in groups. There is also another aspect to tape reading: it is more like read-

in. Under certain conditions they ing print with each character in

Chapter 14

The Ear

By "ear" we mean our total hearing and interpretive system, an intricate and ingenious complete system of perception and interpretation of what is heard: ears, nerves, and mind.

The ears themselves are sensitive over a very wide range of intensities, but have their maximum sensitivity and selectivity at low volume levels. Setting the sound volume level just high enough to be clearly readable, both protects the hearing and improves performance. The ear responds to what it hears first.

Pitch Of CW Signal

The ear is sensitive to pitch. Few people can accurately remember pitch ("absolute pitch"), but most have no trouble detecting changes and differences in pitch. Not many seem actually to be "tone deaf." The usual pitch range used for CW is between 5ØØ and 1ØØØ Hz. Some find

terference is about 500 Hz.

Those with serious hearing losses - who cannot hear certain pitches, or who cannot distinguish code signals in the usual pitch range because their ears "ring" where the spaces should be - may find a lower pitch (e.g. 3ØØ - 4ØØ Hz) helps. Sometimes using a buzzer tone, or adding white noise to the tone may enable them to hear properly. (Note: Avoid the use of has a delay in starting to sound. This distorts the timing.)

The usual narrow bandwidth of tone for CW is uncomfortable to some people and may become monotonous, uncomfortable or unpleasant. The narrower the pitch range the more frequent the complaint. They find a more complex tonal pattern far less tiring and even pleasant. However, when interference is present more complex tones become a hindrance.

Sensitivity To Duration Of Sound

In the perception of rhythm the human ear will adapt itself within rather wide limits in the actual duration of sounds. Our judgment of the duration of a brief sound is poor, perhaps because of a persistence of sound (like persistence of vision), yet we can judge the relative length of brief silent intervals rather well. (This is probably why the telegraph sounder has worked so well for receiving American Morse, where rhythm patterns are complex.) Thus, "If we take care for the spaces, the 'marks' will take care of them-

the best pitch for copying in in- selves." Some students may have difficulty distinguishing dits from dahs. (The normal ratio is 1:3.) For them it may help to overemphasize the length of the dahs at first by lengthening them from 3 units to 4. (It is interesting that in American Morse the dahs tended to become shorter than three units, to contrast with the longer dahs of L and zero. Again, it may be the nature of the sounder that led to this.)

an actual buzzer in teaching as it There are good reasons for believing that we must distinguish between conscious perception of duration and what the brain actually is capable of perceiving at subconscious levels. Support for this belief comes from the experiences of those operators who can receive code signals accurately at speeds which far exceed the point where dits and dahs all sound alike. See Chapter 1Ø.

The Ear Can Often Make Sense **Out Of Poor Sending**

The ear is remarkable in being able to make sense out of some pretty badly mangled code, such as is often heard on the air. It is a forgiving organ: by mental adjustment one can quickly learn to recognize and read quite poorly timed code - code whose glaring defects would stand out prominently if traced out on paper. Within fairly wide limits the actual duration of the sound in a rhythmic pattern may vary and still be recognized. However, the spacing within and between characters and words is a highly significant factor.

are less unintelligible than others. nal-to-noise ratio can be increased Better discrimination exists when by reversing the phasing of the the dits are too fast as compared phones: that is, the noise at one to the dahs than!when!the dits and phone is 18Ø degrees out of dahs begin to approach the same length (easily confused). The ear can often read this kind of stuff when "machinery" fails.

The Trained Ear Can Discriminate Between Signals

The normal ear can learn to separate between signals nearly, but not quite, identical in pitch. For many people the ear-brain filter can focus on a bandwidth as narrow as!5Ø - 1ØØ Hz. If one can focus on a 5Ø Hz. bandwidth with a receiver having a 3 KHz. noise bandwidth, a CW signal nearly 18 dB below the noise level can be heard. However, a bandwidth of about 5ØØ Hz., rather than a very narrow one, makes the mechanics of tuning easier and gives freer rein to the ear-brain filter.

It is usually only when the going gets quite rough that we need an extremely narrow receiving filter and then there is the!risk of losing the signal entirely if anything shifts just a little. It has been said that "The amateur ear, trained to dig out signals buried six layers deep in murderous QRM is the most prized ear in intercept work in all the world."

Headphones Are Superior To A Speaker

Headphones effectively double the power of received signals compared to a loudspeaker. The muffs on the phones keep out extraneous noises and keep the

Some distortions of proportion weak sound energy in. The sigphase with the other and the brain tends to cancel the noise. Noise type ear plugs can also help with phones and/or filters to reduce spurious noises

Chapter 15

Timing

Timing Is The Heart Of The Code

Timing is the heart of the code: there is no code without it. Clear intelligibility depends upon right proportions. However, it is true that some distortions are less unintelligible than others, and people can learn to read that sort of stuff - but is it justifiable? Control of timing rests entirely with the sending operator.

For this reason, attention to careful timing is first needed when the student starts to practice with a manual key, especially a straight key, though also with most other types. This is one reason why some good teachers discourage the use of anything but a keyboard by a beginner. Most modern teachers agree that it is important not to specifically mention the subject of timing until the student has learned the alphabet and numbers so well by hearing them that he recognizes their patterns without hesitation.

Some teachers recommend that other than using "dits" "dahs" to verbalize characters,

at all in teaching, but that it all be terns, sense them, feel them, and done intuitively by sound. On the this is best done by hearing wellother hand, some excellent teach- sent code. In actual practice, indiers of the past (before keyers and vidual operators may and do dekeyboards) have insisted on viate somewhat from the standards teaching precise timing, in terms given above. This may be for emof its elements, from the very first. phasis or because of communica-Accurate timing is vital, but it tion conditions, as well as unconmust never distract the student scious individual variations. from the basic recognition of characters by their essential unity Relative Duration And Spacing of patterning: it must not lead to Are Very Important his breaking down the characteristic rhythm of the characters by analyzing them into components.

The Basic Units

contrasting signal to the "dit" is the dah which has a duration of 3 units (111). It is obvious that each dit and each dah must be separated both before and after by at least one unit silence (Ø) in order to be distinguishable: this (one unit) is the normal spacing between parts of a character. Normal spacing between characters within a word (or group) is three units $(\emptyset \emptyset \emptyset)$, and between words (or groups) is seven units (ØØØØØØØ).

is these components of time, sig-successively longer one guish one character from another. almost any conditions. In practice,

they should not be time-analyzed We must learn to hear these pat-

In the perception of rhythm by the human ear the precise duration of sounds is, within fairly wide limits, unimportant. If the longer signals (i.e., dahs) are sub-The basic unit of code timing is stantially longer than the shorter the Baud, which is the duration of ones (i.e., dits), the ear will be satone dit (or "dot"), denoted here isfied. While our judgment of the by 1 for the "on" signal, and by duration of brief sounds is poor, (the equal unit) \emptyset (zero) for si- we can judge the relative length of lence, the "off" signal. The basic brief silence intervals much more accurately.

It has been said: "If you take care of the spaces, the 'marks' will take care of themselves." Spacing, the periods of silence between parts of a character, between characters in a word or group, and between words, is critical to good receiving. Sloppy or hastily sent code can be a terror to receive and understand. (Beyond some speed the persistence-of-hearing effect tends to fill in the small spaces and make us unable to Punctuation marks normally fol- consciously recognize characters.) low the last word with only one [In American Morse with its three character space $(\emptyset\emptyset\emptyset)$ between. "translators", microcircuitry for converting code into print, break down when sending is poor or interference is severe. The human ear and mind, however, can copy rotten code far better than any machine. The "ear" is a forgiving organ: by mental compensation we can quickly recognize and read stuff as passable paper tape would show its glaring defects. In the presence of interlarge extent during fading, the "ear" can be trained to pick out The use of a very weak signal and read it well. (Chapter 11)

Irregularities In Timing

From the very beginning of telegraphy, as soon as the art began to!spread, the individuality of operators became apparent. Little peculiarities in sending stood out to identify each one, just as voice quality and style do in speaking. Mostly these were subtle little things which did not distract from easy intelligibility. But they did involve aspects of timing and rhythm. We hear them today on the CW bands among amateurs using hand keys just as they did among all operators in the past.

however, because they used a For many operators there was a telegraph sounder which marks certain pride in this. However, as a sort of trademark. When such distortion reaches a certain point and becomes habitual, intelligibility suffers. We hear some of these operators today on the air. They do not seem to realize, or perhaps even care about the difficulty they cause. With the advent of the "double speed key", also called the "side-swiper" or the "cootie key", a key which is operated by sidewise movement, with one contact on each side, a new set of peculiar styles of sending arose. Sidewise instead of up and down code, which if it were recorded on motion helped relieve some forms of fatigue, but also the peculiar motion patterns developed a differing signals and static, and to a ferent timing pattern, one that is sometimes hard to copy.

> "bugs", semiautomatic keys (the best known being the "Vibroplex") which soon became very popular, also gave rise to various personal sending peculiarities unless the operator was careful.

Swings

One of the most interesting developments in disturbed timing of hand sending was the rise of socalled "swings." Swing has to do with a change in the normal rhythm of sending, sometimes described as a change in symmetry or lack of it: a peculiar way of forming the characters. Swings most commonly developed among marine operators within a close-knit group having a large volume of specialized communi"Banana boat swing", "Lake Erie swing", "Cuban swing", etc.

The operators of the large United Fruit Co. were especially noted for this. Some have claimed that swings developed as a most effective way of copying the early day spark signals (which sounded so much like static) through heavy static. The basic principle of "sea-going swing" was to exaggerate the spacing between letters when a letter ending with a dah out slightly.

Other individual rhythmic disturbances were common also, such as drawing out the second dah in "Q" (which we often hear on the air today). In order to avoid confusion in the midst of typically heavy Gulf of Mexico static, developed from call letters KFUC, originality, but causes the receiv-

cations. Thus we have the names the rolling motion of boats contributed to forming it. The name "Cuban swing" or "Latin swing" came from the way most Cuban and Mexican operators ran their words together. Sometimes it must have been quite deliberate just to try to be individualistic, such as!a jerk in forming HPCS 4 5 Y Q; a lengthening of one of the dahs a bit in J, 1, etc.; any "funny" little stroke. But these things made them hard to copy by other operators.

was followed by one beginning Early in 1936 the Eastern Air with a dah, and similarly for one Lines (EAL) communications suending in a dit when the next be- pervisor decided to develop an gan with a dit. The spacing before EAL swing for its operators. He and after an!E!within a word was dreamed up the idea of modifyoften made a bit longer for clar- ing a "bug" by moving the staity. Exaggerated dah lengths were tionary dot post a half inch forcommon also in the attempt to ward. This produced a swing like improve readability: e.g., the first none ever heard before. The opdah in C was generally dragged erators did not like it and soon repositioned the post, but it unconsciously influenced the sending of many of them ever after. Recently operators in a foreign navy were found almost impossible to understand at first because of a peculiar rhythm taught by their telegraph instructors.

Others suggested to copy than usual. He introduces

a jerk in his H's, P's, C's, 3's, 4's, 5's, Y's, and Q's and makes one of the dashes of J and 1, etc., a trifle longer than the rest... A tricky swing he makes as an effort to acquire the 'funny' stroke as he goes on. - Consider the other operator!"

Chapter 16

Other Methods

Personal Computers And Keyboards For Self-Learning

For self-learning nothing is superior to a Personal Computer (PC) can push a key and hear each character (and see it in print if some teachers (as Gary Bold) consider it to be superior to private or classroom learning.

- It is consistent, always sending perfect code in exactly the same way.
- It is always available and ready to be used whenever the student wants to practice.
- Most computer teaching programs provide for easy tailoring to the exact needs of the individual student.
- A PC is impersonal and there is never any reason for the student to feel embarrassment, something which often is an emotional deterrent to efficient learn-

- ing in the presence of a teacher or!classmates.
- It can provide both an excellent introduction to the code and growth in skill to any desired degree.

Many Computer Programs Are Excellent

See also Chapter 18. Computer programs have been and some are still available for the Commodore and Apple computers, but most have been for the compatible PC's. They have been of all sizes and varieties, accordor a keyboard where the student ing to the skill, teaching experience and ingenuity of the programming writers. Many provide there is a screen), as often as he for connecting the computer with wishes or needs to get the feel of the transmitter and using the its rhythm. The PC especially has computer as a keyboard Some become such a valuable tool that provide an evaluation of the student's sending skills.

> One of the important features for rapid learning is the degree of!adaptability to the student and the amount of interaction with him that is provided. How flexible are they? Do they provide checks on skill and accuracy? One example of an interactive computer program (Gary Bold's) starts the new student out by having him hear the character, then keying in his identification of it. If his identification is correct, the character is then displayed on the screen. But if he is wrong, his answer is ignored, and the character is repeated until he correctly identifies it. The same character is then presented several more times for his correct response before taking up the next one. If he delays too long in responding, the character

is repeated (and may be displayed simultaneously) until he gets it.

After a number (per student's request) of new characters have A few hams in years gone by have been introduced, they are re- said that they initially "learned peated in random order, and if the code" by listening to fast one is misidentified, it is repeated commercial press dispatches until the student correctly identi- (probably 35 - 45 wpm), which fies it. There are some smaller pocket sized "computers" which are limited to hearing practice only.

Growing Up With Hearing It

Old timer George Hart W1NJM is one who learned the code originally, as he says, by "osmosis" from an older brother who was a ham - just by listening, with no intention of learning it or getting a license. This way he learned frequent letters and operating procedures until one day he disby code. From then on he was hooked! He later wrote: "[I was] practically born with a key in my me as talking."

Learning By Listening To High Speed Code

siasm. We mention it here only to show what can be done if one is determined enough.

Further Comments On Gaining Speed

With many modern computer code programs available, programmable keyboards and keyers, as well as tapes, etc., there are several attractive alternates available. With these, material can be better tailored for our individual needs. The Farnsworth method suggests itself here in the high speed range, too, to allow the mind time to digest and identify characters and covered he could communicate words. Using this, some have found that to set up a character speed in the 5Ø - 6Ø wpm range and then widening the inter-letter hand, so CW [was] as natural to and inter-word spaces initially, gradually reducing them as desired, can speed up the recognition process.

Sleep Learning

A number of operators in the past who desperately wanted to increase their receiving skills deliberately tried sleeping beside their receivers or playback recording equipment (or their line telegraph sounders in the case of landline operators) with fast code signals coming through for several hours or all night. They claimed that within a surprisingly short time they had great increases in receiving speed. This procedure has been challenged, but apparently works for some people.

One ham, who says he can copy at 7Ø wpm and still wants to increase above that, has for years been listening this way every night. Maybe it works for some people, but I wonder if it is actually effective, and also whether they got any restful sleep that way. It is interesting that in the early 192Ø's a group of doctors were being trained to use Morse code. Their teachers tried sleep-learning with them, and found that if the word "doctor" was sent while they were sound asleep during the night, it would nearly always wake them immediately - showing that there is some kind of unconscious receptivity and response.

Another Suggestion That Has Worked

When someone comes to me and asks how to make the 13 wpm requirement for General class, I give them the following plan of working:-

"You need to listen every day to good sending, and I suggest the

W1AW CW bulletins. They are at 18 wpm. Start out the first few days and just listen for no more than one minute. Then turn it off. As you listen, pick out the characters you recognize. Don't write anything down at all the first few days like this. After a few days, increase your listening time to two minutes and continue to pick out as many characters as you can in your head - and don't write anything down yet. Then turn it off, as before. After eight to ten days of this practice, go back to the one minute period of listening, but this time write down everything you can recognize. Try to leave blank spaces where you miss out. Write down every letter you can catch for that one minute period, then turn it off. Repeat this practice for several days, then extend the time to two minutes, writing down everything you can recognize. After several days or a week or so this way you will find your comprehension coming up fairly rapidly because your concentration is improving and you will be surprised how much you can copy in just this short period of time. From here on gradually increase your listening time to 3, 4, 5, 6 or 7 minutes. When you can copy somewhere around 60% of the bulletin materials you will find that you can copy 13 wpm, the test speed, with flying colors. This scheme has worked well for a number of people who had reached speeds between 5 and 1Ø wpm, but had difficulty in advancing. This general pattern should prove of help to others aiming for the 2Ø wpm test or higher."

McElrov's Course and His **Claims For It**

Although this does not fall into **Do About Them** the above categories, here is what was said:-

In the Nov. 1945 QST, p 115, was an ad in which Ted McElroy's Good operators make very few if that the average person will practice several hours the first day, we can tell you ... that you'll be copying That Very First Day, words and sentences at the rate of 2Ø wpm. The thing is that ingenious! Ted has taken one-half the _ alphabet which appears on his chart No. 1, prepared a practice tape which runs for at least one full hour without attention at the rate of 2Ø wpm. You won't copy 2Ø full words in one minute. But each letter you write will hit your ears at a full 2Ø wpm and the space between letters becomes progressively shorter as the rolls go along." Since Ted's receiving speed records were tops in almost every official speed contest, it would be very interesting to see this document. At present, the above is all that seems to be available.

Chapter 17

Common Errors and What To

Both in sending and receiving errors are sometimes made.

Company offered to "send you any while sending, but "errors" this complete course of instruc- do occur both during sending and tion (McElroy's 'Morse' Code especially while receiving under Course) free so you can see for various adverse conditions. These yourself what it'll do for you. It make it necessary for us to keep was said to contain "everything in mind letters that may be mishe has learned in 3Ø years of op- takenly formed or because of erating experience." "Assuming poor conditions appear to sound alike:-

- Dotting errors too many or too few dits are made or thought to be heard:-H/5S/H B/6 V/4 Z/7
- Initial or final dits or dahs missed or confused. (On the receiving end there is a tendency to hear signals as being shorter than they J/1 C/Y P/J Z/Q W/J are):-W/P
- Other characters which beginners may confuse, particularly:- F/L G/W Y/Q 6/5 Errors that the beginner or trainee experiences in his own work can be turned into advantages.

Specific errors that are often repeated show us where we need to give special practice. If we tend to confuse two characters, we can eliminate it by hearing them one after another until their differences in rhythm become obvious to us.

When we look over our copy and find non-sense or obvious missed out areas, the correction can often be made simply from examining the!context. (This will!generally not work for numbers, scrambled letters or call signs, where there is no repetition to help out.) Normal procedure when you catch yourself making an error while you are sending may be handled something like this: -

- stop, indicate error by "?"
 (or by eight dits), then repeat the last correct word (especially if it is short), and then the one sent wrong and continue on, or
- _ in rag chewing unimportant matter, simply stop a moment and restart with the word mis-sent,
- similarly, if it is a long word and the first syllable or so has been correctly sent, and it is a word which the receiving operator surely will immediately understand, just pause a moment and then go on with the next word.

(The pause will indicate to him the problem.)

Chapter 18

Computer Programs And Tapes For Learning And Improving Skill In Code

It is always a bit risky to try to list currently available materials and books. These change with time, some for the better, a few for the worse, and some simply vanish from the scene. With that in

mind, the following programs have been found representative, both adequate and good. It is quite impossible here to go into the many details of each program, so only the barest outline is given for information. They all provide a range of speeds and pitch of the tone. Some provide various options of screen or printing capabilities, etc., and/or allow the user to remodel it for his preferences, etc. Some provide various ways of increasing or decreasing speed while sending. All use the speaker in the computer for sound output. Helps are provided on screen in most the of programs. ("Freeware" means that there is no mandatory cost to the user other than that of providing the diskette. "Commercial" means the program is for sale on the market.) Unless otherwise noted all are IBM-compatible.

Morse University

- (\$5Ø)- was an excellent Advanced Electronic Applications program for the Commodore C-64 computer, plugged into cartridge slot, with manual.. It included
- a learning program,
- a proficiency program to increase speed,
- a sending analysis (characters and spacings),
 - a receiving game to recognize characters under pressure and a Morse keyboard to compose ones own code practice sessions.

- Learning was at 2Ø wpm Farnsworth character speeds with a 3 second interval between characters. There were 54 basic lessons, plus 7 which teach the German, Spanish and Swedish characters, if desired. It was suggested that one spend two 2Ø minute sessions each day, and at the end of a month many would have achieved a solid 2Ø wpm receiving speed, and have enjoyed learning. Several options were available.
- Proficiency sent a random sequence of characters with programmable starting and finishing speed. Speed was adjustable(5 - 99 wpm), length of practice (up to an hour), number of different characters (up to 45), size of groups, and length of intervals between characters.

Late Note: "Morse University", now called "Ham University" (because it also covers the written troducing new ones, up to lesson exams) is now sold for Microsoft Windows by Michael Crick at http://crick.com/hamu. This new version also includes a new Morse code game called "Pentode" that was inspired by "Tetris".

SuperMorse By Lee Murrah, **WD5CID**

A great deal of variety was built into this program, which is really a series of integrated programs. A learning phase introduced the W4FOK student to the code characters, a Building speed phase provided variety in practice materials, an long MILL developments by

Enhance phase extended this to as fast as one might want, while a Measure phase provided for testing of skill with built-in or userconstructed tests, and finally an Operate phase. Interaction was provided in several aspects.

Code Tapes For Learning And For Other Purposes

The ARRL, several companies and some individuals which make or have made tapes for cassette repaper tapes for high speed transare of poor quality. The ARRL tapes are of high quality.

The Twin Oaks Associates (mental health professionals) offered code training programs. Three courses using cassettes and an instruction book, emphasized learning by ear - mentally or verbally recognizing what is sent automatically. Course first side, without writing anything anything. Side one first sounds

rator immediately identified it. Then did the same thing on the second side, reviewing all previous material without the narrator. This is to train ear and brain to work NuMorse Professional is a brand together first without the complication of writing. After comfortably mastering the first tape, go to the second, etc, through all six tapes. The first tape presents the characters E T I A M N which have one or two elements. Each subsequent tape adds characters having one additional element, up to the fifth tape where numerals and punctuation are introduced." To be practiced 3Ø minutes a day. The Study Guide detailed the methods and theories used. --The two other courses take the student up over 13 wpm, and up over 2Ø wpm.

In the past, as noted in Chapter 25, the Instructograph Co. and the Teleplex Co. were the best known corders for learning up to the makers of punched and inked 2Ø+ wpm seed range and higher, paper tape machines for code inand some have prepared punched struction and training and used both by commercial operators mission and reception. Some of and by amateurs.. Commercially these tapes are excellent, but some the Boehm inked tape and the Kleinschmidt perforated paper tape machines were the most commonly used. We mention these here because they were sometimes used for teaching or practicing the code, but much often for commercial more transmission of code at high speeds.

1, alphabet took to over 5 wpm. Similar systems were manufac-"Practice listening through the tured during WW-II by Ted McElroy's company. With these down or rewinding to pick up machines the operator would prepare the tape for transmission, either on a typewriter keyboard or

with a special three-key device, arms or shutters making block for transmission. Transmission patterns (at night some used light speeds of the tapes might go up to configurations) for distance sigseveral hundreds of words per naling within line of sight. minute when conditions were good. At the receiving end the equipment would reproduce the incoming signals on a corresponding paper tape, inked or otherwise. The receiving operator was trained to read the tapes much as the good reader of ordinary print does, by words or phrases. He would read the tape as it was pulled past his eyes in a sort of track while he transcribed it on a typewriter at comfortable speeds. Typing speeds of $6\emptyset - 7\emptyset$ wpm seem to have been typical. McElroy prepared and promoted materials for building up these skills on his equipment.

Chapter 19

A Brief History of Morse Telegraphy – Part I

It would be very interesting to know the thinking behind the development of the original Morse code. It had to be tied in intimately with the limitations of the electro-magnetic mechanisms being designed to transmit and receive it. Records show that beginning as early as the B.C.'s reflected sunlight (heliography) by elementary signaling. By the A.D. phabetic code formed by the con-

All these systems (often aided by the use of telescopes) were subject to weather and visibility limitations, and generally required at least two operators at the receiving end - one to look and the other to write. Where considerable distances (a hundred miles or more) were involved relay stations were established. These signaling systems conveyed a symbolic message or spelled out words for visual reception. A few electric or electrochemical systems were developed using some method of spelling out words by transmitted letter symbols. Morse's system was not the first to use electricity. During the early 18ØØ's several electrical and electro-chemical systems (which overcame the visibility problem, which was complicated by weather conditions) were invented and used. Some of them were quite ingenious, but tended to be cumbersome, rather slow and troublesome to maintain.

Morse's ingenuity was in combining a simple mechanical system with some sort of "linear" coding. Samuel F. B. Morse ingeniously foresaw the day, and lamps, lights or fires at newly discovered principle of night, were used for some kind of electromagnetism in combination with some sort of "linear" cod-17ØØ's (and well into the ing as the key to developing a 18ØØ's) several semaphore sys- truly practical telegraphic system. tems had been devised and were It could provide the relative simin rather extensive use in Europe plicity and ruggedness needed for and elsewhere. These used an al- the equipment. Like Marconi half a century later, his vision to comfigurations of two or more signal bine these newly discovered principles and the entrepreneurial

drive to bring them into use made critical, but it was a tedious, slow telegraphy what it became in the and clumsy system (as well as field of communication for many being rather subject to errors decades. Two features were which could only be found on needed: equipment and a suitable deciphering). Not much ingenuity code. As originally conceived it was required to develop the code was to be a self-recording system, symbols for the digits: he simply inscribing the code signals on a used from one to five dots to repstrip of paper tape to be read by resented the numbers 1 -5, and eye. There was no thought given extended this through 9 and zero to "reading" it by ear alone.

The Original Morse Code

His coding system begun in 1832 was a translation system consisting .. @ ... @ @ @ of two essential parts:

- a two-way code book or dictionary in which each English word was assigned a number (and in order to spell out proper names, unusual words, initials, etc., when necessary, each letter of the alphabet was also assigned a number), and
- a code symbol for each digit from \emptyset - 9 to represent that number.

recognized that a receiving op- sons been assigned a number.) erator could easily read by eye up to five printed dots, but that a larger number of dots would be more difficult to read quickly and accurately, and would be more subject to error, as well as taking longer to transmit.

With such a system, the duration of the dots and spaces was not by a longer short space following (here indicated by the symbol @).

Here is his code:- 1 2 3 4 5 8 9 Ø @

With such a system, the duration of the dots was not critical, but the relative spacings were important. What a tedious, slow and clumsy system it would have been (as well as being rather highly subject to errors which could only be found on deciphering). The overall idea was ingenuous, and the actual code signals used for the digits were simplicity itself. But his coding system was the weak link in his whole system, and would hardly find wide acceptance. So, the sender would convert each (Later, this code-translation-book word to a number, send that num- method was applied in China ber and the receiver would then where it made sense to convert the convert it back again to the Eng- Chinese characters to numbers, lish word with a reverse diction- using an already available stanary. In devising the symbols for dard Chinese dictionary in which the digits, Morse seems to have each character had for other rea-

Who Invented What We Call **The Morse Code**

Chapter 2 of George P. Oslin's book "The Story of Telecommunications" opens with these words:

"Ask almost any American who invented the telegraph, and the

William G. Pierpont NOHFF© 1932-2001

answer will be 'Morse', but he did not create the dot-and-dash Morse code, the Morse key, or the stylus recorder."

Who was Mr. Oslin, and where did he get this information?

He was a journalist who later became public relations director of Western Union. To prepare this book he exhaustively investigated newspaper articles, magazines, books and more than 100,000 letters and diaries of those involved and condensed it. (He was 93 years old when the book was published.) Pages 13 to 28 are devoted to a summary of the origins of Morse telegraphy, from which the following quotations come. Previous publications had only hinted at what Mr. Oslin has said so clearly. (The numbers in parentheses refer to pages in his book.)

In order to understand the confusion we need to realize first that "Morse's craving for fame was so strong that he postured, pontificated, tried to convince everyone he was great, and was zealous in defending his claims." (28, note 27) To blow up his importance, Morse on several occasions made some quite false statements and exaggerations. It is too bad that he refused to give credit where credit was due, for he would have showed himself a greater man by it. From the very first, Morse made strict contractual relationships whereby he alone was to be credited with all advancements and improvements: all credits for whatever anyone did for him would [publicly] belong to him alone. Yet in a letter Vail, his ex-

pert assistant, wrote on March 11, 1853 that "his agreement with Morse provided 'that whatever Mr. Smith, Dr. Gale, or myself should invent or discover, going to simplify or improve Morse's telegraph would belong to all jointly" (24).

However, Morse never shared any of this, and constantly cut Vail off from any public recognition for his work. Because of this, we know almost no details about the development history of the alphabetic versions of the code. We can be sure that if this code had been the work of Morse himself, he would most certainly have carefully elaborated every step of its development. (This is one clue previously published materials provide us.) A second factor was that they were physically separated during most of the first six or seven years: Morse was in New York City while Alfred Vail was working independently Morristown NJ. This is only a distance of about 3Ø miles by air, but travel was difficult in those days.

see this in the following: "On October 18, 1837 Morse wrote to Vail: 'I long to see the machine you have been making and the one you have been maturing in the studio of your brain.' Later Vail invited Morse to Morristown, where the artist realized his cumbersome picture-frame equipment [for recording the signals at the receiving end] was to be replaced by the practical and simple Vail instrument. Morse was so upset, Baxter said, that he became ill and was in bed for some weeks at the Vail home." (21) (Morse's

assistant in the latter part of 1837, Morse's telegraph system would no doubt have been a failure.

Vail was not only a skilled technician, but had a wider perspective, and must have quickly seen that Morse's complex translationcoding system and its equipment were not really practical: there must be a better way. "It is evident that Henry showed how to telegraph, Morse planned a cumbersome system to do it, Gale made valuable contributions, and Vail developed the code and instruments necessary for successful operation." (25) On October 18, 1888, over 4Ø years later. Alfred Vail's widow wrote to H.C. Adams, president of Cornell University: 1888: ".. Prof. Morse ... sent for me, and on his dying bed [he died 2 April 1872, almost 81 years old], with the forefinger of his left hand raised and moving to give expression to his words, he said: 'The one thing I want to do now is justice to Alfred Vail." (27 note 18) As for his coding system, "Morse's caveat of October 3, 1837, and his letter to Vail on October 24, 1837 announcing the completion of his dictionary of numbers for words did not mention a dot-and-dash alphabet." -- However, he kept working on it until 1843: "Six years after Vail created the Morse code [1937-8], Morse wrote to [F.O.J.] Smith about the numbers-for-words dictionary he was preparing." (23-24)

Vail, in a letter to his father and brother February 21, 1838, regarding a demonstration he had

feelings were badly hurt.) If Al- just given to the President and his fred Vail had not joined Morse as Cabinet: "... The President proposed the following sentence, 'The enemy nears . . . It was then put in numbers and written on the register." (27, note 16) On p. 39 the caption under picture 2.5: "Alfred Vail who created the Morse telegraph key and sounder and telegraph code at Morristown N.J. while Morse was in New York devising a number for each word commonly used. Morse's idea was to transmit numbers instead of words to send messages." "The Engineering News of April 14, 1886, stated that 'credit for the alphabet, ground circuit and other important features of the Morse system belongs not to Morse at all, but to Alfred Vail, a name that should ever be held in remembrance and honor." (24) F. O. J. Smith wrote: "It is evident that Henry showed how to telegraph, Morse planned a cumbersome system to do it, Gale made valuable contributions, and Vail developed the code and instruments necessary for successful operation." (24-25) "Vail watched Morse gradually eliminate him from credit with mounting astonishment and anger, making no public outcry because Morse, involved in a multiplicity of court battles, required all possible support to preserve the patents. When Morse later referred to Vail and his father merely as 'furnishing the means to give the child a decent dress,' Vail supporters boiled, and telegraph journals contained many strong words." (24)

Vail's Thinking

know the thinking behind the decode. It had to be tied in inti- confusion in distinguishing bemately with the limitations of the electro-magnetic mechanisms Vail did some testing to try it out. being designed to transmit and These interesting aspects seem to receive it. Factors which no doubt have gone completely unreported strongly dominated Vail's thinking were: brevity, simplicity and accuracy.

Accuracy requires that the receiving operator be able to distinguish immediately between similar characters without confusion or hesitation. (We must remind a record by eye on a strip of run-"speed" was commercially im- letters." (23) portant, it was by no means so By January 1838, about three pressingly demanding in the mid 19th century as it is today. Starting with Morse' simple off-on signaling system Vail developed this original idea into a truly practical alphabetic concept, one that does not require further one signal-on duration. (Did musical rhythms also suggest the internal character spaces?)

Morse' code-dictionary concept. Note: Although Morse, in writing out his code dictionary, is said to have written a dash in lieu of five dots, there seems never to have been any hint of his using such a signal element in his code itself.

We cannot help wondering how he determined that the use of It would be very interesting to longer-than-normal internal spaces between elements would velopment of Vail's "Morse" not cause the receiving operator tween characters.

in contrast to the attempt to associate the briefest code symbols with the most frequently used English letters, which is well reported (however, as if it were Morse's own work). "In November and December 1837, when Vail built the instruments, he visourselves that at this point in time ited Louis Vogt, proprietor of a Vail was thinking only of reading print shop at Morristown, and, over a case of type, learned which ning paper tape, not about re- letters of the alphabet were used ceiving by ear as was done later.) most frequently. He assigned the We must also realize that while fewest dots and dashes to those

months after Vail had joined Morse, he had produced the first practical "Morse" code, a purely alphabetic code, which included the use of dashes as well as dots and internally spaced characters. [However, at this point not every translation. We may suspect that letter had a separate code charachis key idea was to use more than ter; several (J = G, Y = I, V = L, and S = Z) were combined. This would be ambiguous for receiving by ear, but more easily handled This was totally different from reading by eye from the context of the inscribed tape record.] This alphabetic code would have made coding and decoding almost perfectly straightforward, and let overall transmission speed jump up immediately to about ten wpm. However, he did not tell Morse about it:-- according to informa-

Neither the final 1844 code nor its successor, the International Morse code, is perfect. Perhaps no code could be "perfect" for every application, but it proved practical, and together with the promotion of the telegraph instruments it came into wide and of the letters.

Chapter 19

A Brief History of Morse Telegraphy - Part II

The Original Morse Code Modified In Europe

Morse telegraphy was introduced into Germany in 1847 by a Mr. William Robinson (without authorization by Morse). There the Marine Dispatch Service between Hamburg and Cuxhaven, a communication system for shipping, was using an optical system, useless under bad weather conditions. They became greatly interested in the potential of this electric all-weather system.

be confused: I, O and EE; C, R, S, eliminate the internally spaced "on" signals, T, L and Zero lengths: a dot and a dash. Even mission longer, it meant less skill was required to achieve the same level of proficiency and accuracy of communication. He retained A BDEGHIKMNPSTUV just as they were, used I for both I and J, and then formed new code characters for those deleted, and for the numbers, etc.

successful use. Its efficiency in Other German and Austrian states other languages will vary, de- soon adopted the Morse system, pending on the relative frequency but each state modified the Morse code independently, making interstate communication difficult. In 1852 the German and Austrian state telegraphs convened to unify the codes in use (as well as the tariffs).

Their principles were:

- uniform dot and dash elements (and spacings),
- letters to be no more than four elements long,
- numbers to be five elements long, and
- punctuation six elements long.

They took Gerke's alphabet as the basis, but changed his O P X Y and Z to the present "International" forms, and developed the One of their officials who was also present systematic number system, an engineer, Frederick Clemens etc. They made this code their Gerke, immediately translated official standard on 1 July 1852. -Vail's book on the telegraph into The present form of J and other German. Equipment

Morse's original receiving system was a clumsy recorder which made marks on a paper strip pulled along by a clockwork under a magnetically operated pencil, pen, or stylus. It presented an "on-off" record which was then read by eye. Vail created a much superior recorder. There is plenty of evidence that even Morse and Vail had learned to distinguish most letters by ear during the first few months of their primitive sending.

As early as 1845 some other operators could identify most of the code letters by ear as they listened to the clicking of the recorder. By 1846 many regular operators were doing so, or could. However, there was great reluctance on the part of local office managers to accept this method of copying, and some strictly forbad it. The operators who read by ear had to keep the paper tapes as proof of their accuracy, and offered a means of correction. (In copying, operators often used abbreviations which would be intelligible to the readers).

Morse's original sending device was a sort of type-setter's ruler with dots and spaces. Vail's first simple key, predecessor of later hand-keys, was designed about

tered the service as a messenger boy at age 14. Within a year he became an operator at Frankfort KY, and was reading by sound. Not only so, but he had also taught himself to send and listen at the same time, writing down an incoming message while sending another.

Some other operators by that year were listening to a message or two, then writing them down later.

On the first of May 1847 the Albany Evening Journal reported that a business man named W. C. Buell was sitting in the telegraph office listening to the incoming messages when the operator's tape printer fouled up. Buell was found to have correctly "read" and remembered what had been sent.

That same year a Louisville broker, who had been sitting in a telegraph office, was fined and jailed for listening to market reports coming in and not paying for them (because he had no operator's license)! That same year, a Mr. Books, operator at Pittsburgh, wrote out a long message by sound alone. Receiving by ear alone was proving to be not only possible, but practical (and time saving). Nevertheless, some offices were slow to accept receiving by ear alone, and required all messages to be recorded even 184Ø. It was a simple flat spring though the operator read by ear.

that not only did he copy accuinvented in 1856 and was used military honors or pay.) extensively and almost exclusively during and after the Civil War, though a few diehards persisted in requiring the old recorders to be used.

Early Day Operators Up Through The Civil War

Telegraphy grew up with the railroads, making train dispatching, etc., easier and safer. At first, most telegraph offices were in the RR stations. Each station, as well as many other important locations (such as switching points) was manned by an operator. There were many more "country" and small-town stations than "city' offices. Most operators came from the country and small towns where they remained, but some were attracted to the advantages of city offices.

man's occupation. The majority ranged from 14 to 18. Some were in their 2Ø's, but few above that. Many of them became superb operators, very accurate, fast and reliable. Almost all were completely trustworthy and loyal.

In 1852-3 an Erie RR conductor They refused to divulge the conrefused to accept train orders re- tents of messages to other than the ceived by ear, and complained to addressees. Many of these young his superintendent about the op- chaps who had served in railway erator, Charles Douglas. When and public telegraph offices be-Douglas was reproved, he insisted came operators for the armies of on being tested, and demonstrated both sides during the Civil War, frequently doing service far berately for short messages, but also yond the call of duty, and at great for very long ones. Thereafter the personal risk. (Although they Erie RR officially permitted were usually stationed right on the copying by ear. The sounder was front lines, yet they never received

> In the early days pencils were used to copy, and an adequate supply of sharpened ones was kept at hand for each operator. Later, many telegraphers copied with pen and ink (in beautiful Spenserian script - think of the risk of blots with the old steel pens!), at speeds that ranged up to 3Ø-35 wpm: neat deliverable copy.

Operators After The Civil War

This was a period of growth, both in the number of RR offices, and especially the size of big-city offices. Women in large numbers began to become operators in the city offices because it was cleaner and more respectable work than domestic or factory labor. There were several categories of operators in the city offices: those han-Telegraphy was mostly a young dling slow traffic from country places, those handling higher were boys whose ages ranged speed material, financial report from nine upwards. Most of them operators, and at the top, press (news).

> The goal of most male operators was to advance and be able to handle high speeds accurately. These were honored men with the highest pay. In a city telegraph

office it was common to "haze" speeds too fast for him and watch on, he took it pleasantly, he was considered "initiated" and accepted into the telegraphic fraternity. But if he was infuriated or freshman.

When typewriters became practical in the 188Ø's they began to be used in American telegraph offices. A superb operator was said to be able to copy $5\emptyset$ -6\Ø wpm without trouble, and many of these were said to have copied regularly 5 - 6 words behind to do this.

The Introduction Of Wireless

When Marconi entered the scene with his wireless, the "Continental" or "International" Morse code was in wide use everywhere except in America. Wireless was then primarily - in fact, almost solely - used where wire lines could not be strung. That meant that it was almost entirely ship to shore or ship to ship. American operators were American-Morse trained, and soon had to add "Continental" code to their repertoire, using both codes: American Morse among themselves and "Continental" with other operainterchangeably as needed, on a moment by moment basis.

For a period of time up to about a new operator. The others would WWI this became a requirement. arrange to have an unusual or However, using the somewhat garbled message sent to him, or faster and very "ditty" American more often a message sent at Morse with the early spark transmitters made copying difficult him sweat and worry it out. If, whenever static was present. The when he looked around at their static and the signals tended to amusement and realized it was put sound too much alike, and at the low radio frequencies then in use, static was heavy during at least half the year. During this period the U.S. Navy developed an enupset, he was considered still a tirely different set of code symbols, probably for this reason, but they were abandoned in favor of the "Continental" code just before the U.S. entered World War I. It was about the same time that the "Continental" form of Morse code also became standard in the U.S. for commercial and among almost all radio amateurs.

When Were The Terms Dit And **Dah Introduced**

The March 1926 Wireless Magazine refers to the 1923 Transatlantic signals of (F)8AB as flutterv 25 cvcle with 'dahdahdahditdit didah dahditditdit". Were there earlier examples? With a sounder, instead of 'dits" there are "iddies" and for "dahs" "umpties" to distinguish the two types of clicks. Another description was "klick, kalunk". In addition to this, of course, was the spacing between words. Good sending had to be relatively precise.

Accuracy was demanded of tors. Many became highly profi- commercial operators: they were cient in both codes, using them rated on the quality of their sending. A sender or receiver who had to repeat or to ask for repeats

could be disqualified. It was not First, the old Morse differs from merely a matter of courtesy, but International in four aspects: of economics: errors meant delays for customers and cost time and money to the telegraph companies. The good telegrapher adjusted his relative lengths according to the perceptive skill of the receiving operator, by making 2. larger or smaller differences in the relative lengths.

One operator reports from his experience that careless Morse MORSE: sounded worse on a sounder than on CW. Words with lots of Old Morse letters: joy!jack jail Japan jelly jewel jiffy join jolly jungle jury quick quality queer equip 3. quote ill long loss late labor loyal legal limit lip

Chapter 20

Learning the American Morse Code

Comparisons

Here we consider how to go about learning the other code. Since most of us know the International (formerly called "Continental") code, how do we go about learning the old ("American") Morse landline code? Do not use the following comparative lists in any way to learn the American Morse code. Their purpose is solely to show the differences between the This does not include other effects on the structure of certain old Morse landline circuits was characters due to the Morse inter- used extensively. It must be heard nal spaces and the special length- to learn it. ened dahs. They affect rhythms.

- The following characters are the same in both codes: ABDEGHIKMNST U V W 4 (2/3 of alphabet letters)
- A number of International characters represent different letters or numbers or signs in old Morse:

F J Q P X 1 5 7 8 9 . ?

INTN'L: R C F 5 L P o Z 6 X ? /

Certain old Morse letters contain internal spaces which make them subject to possible misinterpretation as two letters:

0 C R Y

might appear to be

IE EE EI II SE

4. Certain letters in old Morse are different from any International character for English:

L = a longer dah,

 \emptyset (zero) = a still longer dah (see below).

The following numbers are different in old Morse from any International English character sound: 2 3 6.

two codes, and particularly the punctuation, which differs and in

Timing

There seem to have been no rigid "standard" timing relationships in American Morse as compared with International Morse. That is, the duration of a normal dah is stated variously as being two times or three times the duration of a dit. (My own impression is that it tended to be somewhat shorter space was often felt necessary, than the corresponding dah in International code. This might have been done to save time and yet to keep the careful distinctions between a dit and the definitely longer dah for "L", which nominally was considered to be twice as long as the normal dah.) The important thing was to clearly distinguish between "E" and "L" and "T". Zero (Ø) would be intentionally longer than "L" when there would be a risk of its being misread, but otherwise would be about the same. (Some have described "L" as being as short as 4 or as long as 7 units, and zero as short as 5 or as long as 100 units. There seems to have been better agreement on the spaces.)

The important thing was "This is communication. Things should Morse code: have to be sent only once. Having to repeat wastes time and money." Are the words and numbers being clearly understood by the receiving operator?" Commercial telegraphers were rated by their accuracy first and speed second.

In the same way, the space in the internally spaced characters (3) above) is usually stated to be the duration of two dits, but tended to

be shortened just enough to be clear, so the receiving operator would not be confused. The spacing between letters in a word nominally appears to have been the duration of 3 - 4 dits, and between words about the length of 4 - 6 dits. Before and/or after the internally spaced characters a slightly longer than normal letter depending on the code environment.. Again, these values would tend to vary according to the skill of both operators. The object was, as always, perfect copy with minimum time to transmit, leaving considerable flexibility to the individual operators. Yet the demands of this code for accurate proportioning -- intolerance of the least bit of hesitation, key up or key down (e.g., the person who sent the word "telegraph" in such a way that it was copied as "jgraph") -- show how much more acute timing is in American Morse in contrast to International Morse.

No Need For Confusion

Three general features distinguish old Morse from International

Most obvious is the difference in basic rhythm: International has a distinctly "regular" sort of rhythm, while old Morse has a catchy sort of apocopated rhythm - it marches in a striking sort of "go and halt" way, which, when sent by a skilled operator, is unmistakable.

- Along with this is a rather obvious "ditty" characteristic of old Morse by contrast with International.
- Not quite so obvious is that old Morse is about 10% faster than!International when the same lengths of dashes and spaces are used in both codes (that is, it will take about 10% less time to send the same text). Interestingly, old Morse also requires about 15% less effort to send. It tends to be more of an art form, with considerably more variation in "fists," or sending styles.

At first sight, with some characters the same and others different, confusion between the codes might seem considerable in learning the other. - Take heart! Learning It In a personal letter in 1942 Mr. R. J. Miller, a skilled teacher with the How should we go about learning old Teleplex Co., wrote: "One old Morse? -- First of all, we have who is expert in only one code, to hear it properly sent, because e.g. American Morse, can master its rhythms are different. We Continental Morse in ten days to should have little trouble with two weeks and be as expert at the recognizing it on the air: its pecunew code as he was in the old liar rhythms and "dittiness" will code. This is because his mind is quickly identify it. But also we trained to recognize the quick will find we can easily read many sounds. This theory has been common words because they proved many a time.

Notice his words carefully: "expert" and "his mind is trained to recognize the quick sounds.' These are not trivial words. It is the operator who already can handle the one code like an expert, because his mind has been well trained to recognize the letter sounds instantly when they are sent at a good speed, who is going to learn so fast and well. Just how

Mr. Miller defined "expert" not pinned down, but we can assume that such an "expert" was better than the minimum requirement for a commercial radio operator of those early days. It is probably safe to say that a person who can easily handle the code somewhere in the 25 - 35 wpm range will find Mr. Miller's words to be true, if he puts himself to it.

From this we may assume that those of us who are less skilled and want to learn old Morse may expect to take somewhat longer to get there. (Is it possible that in learning the second code in the proper way we may actually improve our skill in the code we already know, since immediate character recognition is the key point?)

sound the same in both codes (e.g. "and, the, it, but, these, thing," and many others) -- that's an encouragement: we don't have to relearn their sounds. Listen to get the swing of it, then practice with your key, imitating the experts. This will help reinforce the sounds.

Consider the following suggestions:

- 1. Just ignore the idea of possible confusion: over the years many operators with various degrees of skill, from quite modest to expert, have managed to use either of both codes with no difficulty. In early "wireless"days a commercial operator was generally required to do this, and many of them were not very fast operators.
- 2. You already know twothirds of the alphabet and one of ten digits: so you don't have to give these any special thought at all.
- 3. Think of all the characters that are different - different in the one code from those in the other separately. Learn and think of each one of them as part of the code system to which it belongs. Don't mix or compare them - keep each one separate and distinct from the other: (For example, don't under any condition let yourself start to think: that's "C" in International so it is "J". In Old Morse) There must be nothing standing in between the signal you hear and its immediate recognition as being the letter. (A person who knows German as well as English knows that the letters ch are pronounced differently in German than in English there is no confusion at all. We need to think the same way here.)

4. Remember that learning old Morse is going to be much easier and faster than learning International code because we already know how to go about it and that many, many others have succeeded well. This ought to give us great encouragement and confidence.

Some excellent suggestions come from those who have long known and used both codes. One of these is to use a Morse sounder instead of audio tones to provide a completely different sound environment to help distinguish Morse from International. (If this is done, one needs to get familiar with receiving by sounder. See below.) If one does not intend to use a sounder, there is no point in practicing with it. Some experienced operators see no benefit from it.

So there need be no confusion at all. We can simply go ahead and confidently learn the old, but new-to-us Morse code and enjoy it, using the principles already set forth here. Perhaps some of the old timers who have learned them both long ago may be pleased to give us some additional advice from their experience also.

[Expertly-sent Old Morse tapes may still be available from Cecil Langdoc, 2Ø1 Homan Ave. Elkhart IN 46516. They make for great listening.]

A Railroad telegrapher's story:-a beginning operator was sending as fast as he could with a bug when the other operator cut in with what he copied as "REND

a repeat and got the same copy. earlier code was first used for He turned to his supervisor and wireless. Two factors probably asked: "What's wrong with that acted to effect the change-over: operator?" The reply: "Nothing, the predominantly "ditty" charshe's just saying 'Send slow I'm acter of American Morse sounded a girl.' You've gotta learn the more like static than the Internadifference between R and S and T tional form, and the world-wide and L. Didn't they teach you nature of shipboard wireless opanything in that school?"

Here is an example of all-dot" sentence": Her Irish eyes cry cos she is so sorry.

Learning To Read By Sounder

Learning to read by sounder is no more difficult than by tone or buzz. It is just different. The sounder makes two different kinds of "clicks" which correspond to movements of the key. The down-stroke produces a sharp (high pitched) click to denote the beginning of the "on" signal. The up-stroke is a duller Some Further Comparisons sound, indicating the end of sigprobably find it interesting and a tional channel. challenge at first.

STOW IMA GIRT". He asked for only 5 years later, in America the eration urged a common code. This would have become more demanding as international commercial and amateur operation became commonplace.

American Morse - An Art

American Morse telegraphy is considered by many of its practitioners as a thing of beauty, a work of art. The "tune sung out" by a local sounder "outranks the most precisely tuned aircraft engine in terms of sheer beauty", according to one old timer.

nal ("off"). The length of the If the identical duration of the intervening silence between them basic unit of time (the dit and unit corresponds to the duration of the space) is used for both codes code element, distinguishing a dit while sending the same message, from a dah. Practice first with a the skilled American Morse opstring of dits and then of dahs till erators will have completed the you get the hang of it, and then message while the International with some common words until operators are still sending and you get familiar with this method receiving. The message will in fact of hearing the code signals. (Use actually have been handled at a letters which are common to both rate about 45% faster* on the codes - see 1 above.) You will Morse line than on the Interna-

*) Here the skilled old Morse op-American Morse was designed for erators will normally be using operation over wires, where static shorter dashes and spaces (as and other interference are absent noted above) than their Interor minimal. Although the Inter- national peers. This, combined national form of the code was de- with the 73% shorter average letveloped and adopted in Europe ter and 65% shorter number in viously cited 10% faster.

Therefore, when we read of the speeds achieved under American Morse operations we need to recognize that the sending operator is having an easier time than the corresponding International operator, but the receiving operator is under the same burden, but needs a more acute ability to discriminate small differences than Words which contain only letters his corresponding International operator.

In addition, when both have completed sending the message, the Morse operator will have used only about 91% as many keystrokes and about 85% of the total work or energy expended by the International operator.

These gains are achievable at a cost. First, the American Morse operator must learn to make some finer distinctions in sound than the International operator. He must readily recognize the internally spaced letters (C O R Y Z) and the lengthened dah characters (L and zero) as distinguished from what might be their equivalents, and he must generally live with closer spacing between characters and words. There is also the problem of the difference betelegraph office and reading signals over the air where static and interference can cause loss of signal components.

Ambiguities introduced by the spaced letters and the shorter dahs in American Morse under radio operation stand in sharp contrast to the standardized durations in

old Morse accounts for the appar- International, making the latter ent discrepancy between the pre- easier to interpret under adverse conditions. I suspect that Old Morse operators under radio conditions tend to lengthen (or exaggerate) their time intervals (signal on" and spaces) to aid in copying. If they!do so, then the time gain is less.

From the MILL ØØa Operational Notes

by Jim Farrior W4FOK who originally learned American Morse

A considerable variation exists in the way American Morse is sent by different operators, and there is no rigid standard. Although it is not typically sent exactly that way, it is convenient for some purposes to assume that the Morse standard is the same as the CW standard, except that certain Morse characters contain a wider space between two of the dots, and the Morse word space is 1 unit shorter than the corresponding CW space. Also, Morse L is a dash approximately twice the length of the standard dash, and the Morse zero is a dash approximately three times the length of the standard dash.

This results in the following Morse "standard":

dot = 1 unit,

normal space = 1,

special Morse space = 2 units,

dash = 3 units,

Morse L = 6 units,

Morse $\emptyset = 9$ units,

character space = 3 units,

word space = 6 units.

all aloe career clap clay clear cliff clip Although I haven't spent much practice time with learning American Morse, it isn't easy for fail jail jeer jello joy jury leap lily lop me to distinguish the different lengths of dahs and to perceive the spaced characters as units, rather than e's and i's, without paying close conscious attention to them.

> My suspicion is that I have for so many years been trying to read poorly sent International Morse that my perception of these small differences in length and spacing has become badly desensitized. -American Morse operators could never have lived with that kind of carelessness. They would have shuddered at such sending. Poorly formed International Morse, where the dits and dahs are often grossly distorted: on the one hand it is sometimes hard to tell the difference between dragging long dits and clipped dahs, and on the other where the dahs are far, far too long for the sending speed, with many simply irregularly sent. Add to that the careless spacings internally between letters within a word, and one has to do a lot of mental adjusting to understand such poor sending.

Chapter 21

Methods Not Recommended

In almost every subject we may study there are efficient and inefficient ways to go about learning it. It seems foolish to go about learning in a hard way, if we know of an easier, better one.

Doing It the Hard Old Way

Beginning somewhere back in the later 18ØØ's, even the best schools for telegraphers started teaching the new student the Morse code by giving him a printed chart code to "memorize" visually. The implications were that learning the code is going to be hard and will take a long learning is like this: time to master. So the student expected it: that's why, if he could The student afford it, he went to a telegraph school. Without realizing it, he was thoroughly prepared to begin in the worst possible frame of mind and way.

This attitude carried over naturally into the early days of amateur radio and continued for a long time afterwards. The whole atmosphere was "it's hard". Isn't that still the attitude of most people today? We need to get rid of the idea that it is hard - it isn't. Experience has shown that the best teachers have avoided that idea completely. Learning the code, as well as using it, ought to _ be an enjoyable experience, easy and even "fun". Such teachers also ignore a student's errors in order to avoid negative reinforcement.

The old way of learning by a visual memory or by counting dits and dahs analytically is almost guaranteed to!produce that old and famous "plateau" at the fastest speed the mind can handle such a burden at a conscious level usually around 7 - 1Ø wpm. Those who take each code character and put it through such a mental routine to get the letter for which it stands are on their way for trouble - they soon get stuck on a plateau.. Why should anyone bother to make the conscious mind go through that sort of thing at all, since it is so futile and is really working against us? The only obvious reason is that they don't know any better.

An analysis of that old way of

- First creates a mental table of the printed characters and the dot and dash patterns (how many and in what order) belonging to each one. Then he begins listening and copying practice and
 - He then hears the sound of character as it is sent,
- Mentally breaks it into so many dots and dashes, and
- May then say the dots and dashes to himself,
 - Which pattern he now looks up in mental table, finds it,
- Identifies it with the corresponding printed character, and finally

Writes it down.

How clumsy and awkward

As late as 1975 George Hart in the August QST (p. 100) wrote "Most code learners start out by "dots" and "dashes" "dits" and "dahs". who are cautioned by an enlightened instructor that A, for examvoice emulation is "didah" even those usually "memorize" by a long sound. . . . Thus, the most people is a counting procethis." How discouraging and unnecessary! He pointed out that There is never any reason to see the way to learn the code is by first hearing the characters it at a speed too fast to count and learning them as rhythmic units of sound - sound patterns. This is the way the ARRL code teaching programs now do it.

Other Discouraging Processes

Many, many people have managed to master the code by methods which we cannot recommend often have experienced great dis-- 12 wpm.

Through the years all sorts of schemes have been devised for "memorizing" the code, and some of them quite ingenious. Most of them involve some kind of visualization: a pictorial or a memorizing the alphabet in terms systematic arrangement of printed or coded characters, based on their Even those structure,!a "chain" of relationships of some sort, adding to or exchanging components of one ple, is not a dot followed by a character to obtain another. A few dash. but a sound whose closest have devised words or phrases presumed to have a sort of 'sound-alikeness" to the code that it is a short sound followed character. Such methods probably would help a person who might initial stage of code learning with sometime need to signal for help in a dire emergency, but they are dure, and no amount of emphasis worse than useless, of no value at on sound is going to change all for regular telegraphic communication.

> the code in written form. Never translate "dit plus dah means A" and then write it, or as another has said: "If you find yourself hearing 'dahdidahdit' and saying to yourself 'Aha, that's a 'C', and then writing it down, you're in trouble - that's translating."

Most of these well-intentioned aids to learning have overlooked the fact that the code letters are an alphabet of SOUND. today, but they have done so at a "aids" have interposed someheavy cost in time and effort, and thing else between the lettersound and the letter. Most of couragement along the way. They these methods present their have managed by persistence to schemes to the eye, not the ear. overcome the stumbling blocks Even those which purport to use and achieve success in spite of sound (such as "sound-alikes") them. But countless others have fail to provide the necessary unity gotten stuck and given up at some of sound pattern (partly because slow speed, generally less than 100 they are too slow, but also because the "sound-alikes" are extrane-

require one or more extra steps - element to the previous one. This translation steps - to get there. was illustrated by large printed Those which require some sort of dots and dashes. There must have analysis (such as how many dits been a good many who started and dahs) of each character in out this way, and in spite of it, at order to identify it, or which run least some of them finally manthrough a series of some sort, also aged to become proficient. I knew have introduced needless steps of one such amateur who got to which inevitably slow the learner around 2Ø wpm that way. down, and usually severely limit his achieving speeds over about five to ten wpm. Avoid them.

Very many of those who origiprinted chart of dots and dashes began the bad habit of counting 13 explains why. the number of dots and of dashes from a mental chart. Then they must decipher the longer characters by counting: for example, to separate B from 6 and 1 from J. Some of these hams were able by much practice, and perhaps realizing the nature of the problem, to overcome their speed plateau. (I knew one experienced ham-exnavy-commercial operator who could go right along at 2Ø wpm this way, but that was his ultimate limit. He loved the code, but could never advance a step further. That was as fast as he could analyze - pretty fast at that!).

Those who have learned by the -"sound-alike" methods, (e.g., they hear "didah", and it sounds like "alike", which they have been taught means "A")!rarely reach even a ten wpm plateau.

One method extensively advertised for many years "taught" the beginner by the scheme "Eat Another Raw Lemon," which was supposed to remind him how each of the four letters E A R L was

ous and distracting). Both kinds formed, each one adding one

The expert teachers tell us that any kind of printed dots and dashes or any other such pictorial impressions will only impede the nally learned the code from a student's progress when he is beginning to learn the code. Chapter

> All such methods violate good pedagogy, because they do not teach the code the way it will be used, as actual sound patterns. They also require the student to learn something (which he must later forget in order to advance) in addition to the sound of the code itself. While these methods may seem to make it easier at first, they actually make it much harder, or even impossible, to advance. The wise teacher and student will avoid these approaches.

- Never even **Look** at a written table of the Morse code before starting to learn, and certainly *Never* attempt to memorize one visually, or have anything to do with software that "shows you the Morse characters on the screen".
- Don't have anything to do with methods that ask you to listen initially to successions of dots and dashes, or

parts of characters. Doing this will **Retard** your progress. Listen Only to complete, correctly sent, characters.

- Never listen to Morse at a character speed of Less than 12 wpm. Use 14 wpm or faster, if possible.
- Don't learn by memorizing opposites, such as 'K' and 'R'. This actually causes some people to confuse them ever after!
- Don't spend lots of time copying random code groups. Reading plain language is very different, and that's what the test requires. Random code groups are popular because computer programs can be easily designed to send them. They do have a place - that is, for first identifying characters and then later practicing any "hang-up" characters, but that's all.

When a old timer, who had "learned" the code as it used to be taught from a printed chart, sound pattern is the letter, it was like a light bulb flashing on. After that he began to progress rapidly.

The Futility of Wrong Practice

Arnold Klein N6GAP said

"For more years that I care to admit to myself, I have been trying to master a simple task: copy code at 20 wpm for the Extra class ticket."

He practiced so much that there was no extended period of free time when he wasn't thinking code. He wore out a cassette player listening to tapes while driving, cutting the grass, sweeping, planting flowers, walking during lunch, using the tread mill at night and while washing the dinner dishes, while watching soft ball games he had the earphones on and copied in his head. He copied code while waiting in the doctor's office, while parked as his wife went shopping in the evening he copied CW on the rig, a gray haired man wearing earphones and writing on a clipboard!

"The results were frustrating. The speeds ranged from 2Ø to 24 wpm and always there was that sense of panic, that I can't keep up" "tailgating" - that was exactly what he was experiencing. The problem was he didn't know what he was doing wrong. Asking those who passed the test resulted in the casual answer: practice. "Well, my practice just wasn't doing it". Magazine articles on copying behind did not relate how to learn suddenly recognized that the the technique. The stock phrase seemed to be that the ability to copy behind will magically appear after enough practice.

> He wrote like this after reading the principles presented here:

> "Mastering the code has taken on a life of its own and I am determined to do it. I have now tried these during the week since getting them and they do work! I am losing the pressure to keep up. Keep calm is my newest admonition. They have given me the an-

swer to the problem I've carried for years."

The methods presented in this book are time-tested practical, working methods.

Chapter 23

Making Sure You're Understood

From The Originator's Stand-

Communication fails unless our message gets across and is understood. Weak signals and poor conditions during transmission (static, interference, fading) all contribute to partial failure to get through. In all of these conditions, telegraphic communication is vastly superior to voice because almost all its energy is effectively concentrated within a very narrow band. Yet it pays a cost for this by taking more time to communicate much more careful of how we say the!same words. In addition, it too can suffer partial loss due to from just plain accidental misunthese losses to a minimum? Let's

view knowledge stockholders property focus on the originator's use of words themselves "words" we include the use of

Feedback And Redundancy

We rarely think much about how we speak when we are conversing. When we speak face to face we can generally tell whether we are being understood or not by feedback through the reactions and responses of the listener. But when our communication is remote, by voice over a wire or the radio, the visual clues to the hearer's understanding are missing. When the telegraph code is the link, auditory clues (tone of voice of a comment or reply, "uh-huh", "yeah", etc.) are also missing. Relatively awkward break-in is the only possible direct feedback while transmitting in code, and it is an ambiguous interruption, until the receiving operator explains his problem.

It is when we speak, whether face to face or by remote means, that most of us tend to use more words than the bare minimum necessary to be understood: this is called redundancy. The degree of redundancy varies from person to person and from situation to situation. Redundancy increases the context from which the hearer to may understand.

When we write we generally are things that are important than when we speak. We give more transmission conditions as well as thought to the choice of words and the way we write them: we derstanding. How can we reduce becomes more circumspect and precise in order to minimize the

to make up for that lack.

In telegraphic communication the tendency, largely because of the time required to transmit, is to eliminate every word which does we think we dare to omit and still have it understandable. (This is especially true when paying on a per-word basis for transmission.)

What we have been saying is this: redundancy helps to insure adequate and more accurate communication. That is, we normally use more words and expressions than the bare minimum required to get our meaning across. Time, however, is a factor working against telegraphic communication. It is not as rapid as speech in terms of words per unit time. In order to balance the time factor against the intelligibility factor, the originator of a telegraphic message generally weighs more carefully exactly what words to use and how to put them together. If he is wise he will also consider the effect of possible mistakes or distortion during sending and receiving which might produce ambiguity.

Repeating And Counting Words

What can we amateurs do to minimize misunderstanding or

reader's possible misunderstand- complete failure of our commuing of what we mean. Since we nications? One of the commonest have no feedback at all, we gener- things is simply to repeat each ally tend to use more words than word or words, or the whole mesthe minimum necessary in order sage. We may repeat only the most critical words or numbers two or three times. (Numbers are almost impossible to correct because there is no significant context to help out.)

not seem to be absolutely neces- Another form of repetition is to sary. We abbreviate in various ask the receiving station to repeat ways - generally down to bare the message back to the sender bones: the minimum required to word by word. This nearly assures express the thought. First we leave perfection. But this, like repeating out words, and then we tend to each word as it is sent, requires at abbreviate what is left as much as least twice the original time on the

> Counting the words in a transmission has long been a common commercial practice, but is not generally used except for message type traffic. It does not assure complete accuracy (exact words and spelling).

Using Redundancy Intelligently

We can often prevent misunderstanding by adding a word or two to a short communication. For example, to confirm a scheduled QSO later in the day, to say "CUL this afternoon," or "CUL in pm" instead of just "CUL" helps insure that the other operator knows that you mean today, and that you are not canceling it (as he might assume otherwise due to some interference, etc.). When conditions are rapidly deteriorating this may be our only hope to get across before further communication becomes impossible.

A little forethought along these lines on the originator's part may pressions carefully.

At The Receiving End

Here we ask "Will I be able to copy (or read) it?" and if I can't, "What is the problem?" - "What can be done to improve the quality of this material I am receiving,"!or "What can be done to make sense out of this somewhat garbled transmission which is all I have?" -- "What is the nature of _ the problem?"

During the communication, speed of transmission is an important factor, one directly controlled by the sender. Both too fast and too slow sending can cause trouble in receiving - here the receiving operator must tell the sender to slow in Hertz or cycles per second, down or speed up to meet the re- while the corresponding teleceiver's needs. Quite naturally, graphic signaling "frequency" is speed of transmission must set be usually expressed in bauds. One within the receiving operator's baud equals one telegraphic elecapability.

It may be that the weighting of the dits is too light and I'm missing some of them. If so, can the sender make them a bit longer The minimum basic telegraphic spot, but he must be told.

In Chapter 14 "The Ear" we have discussed some of the things which can be done to help, espe-

help avoid unfortunate misunder- cially the use of filters. Here we standings. Especially when we look at the filter requirements for simply must get through, and an audio filter. We want a filter conditions are very poor, we which will separate the desired should choose our words and ex- signal and still keep it intelligible. At this point we are not concerned with any of the radio frequencies of the signal as it passes through the receiver, but only with the audio beat signal which is output.

That audio signal consists of

- An audio frequency (the beat frequency, analogous to the carrier frequency of an AM signal), and
- The off-and-on modulation of its envelope (corresponding to the audio modulation of an AM signal) produced by the keying device at the transmit-

The audio frequency is expressed ment (called "unit" in Chapter 28) per second. Since the baud may be unfamiliar, let us examine

(heavier)? Maybe the sharpness of element is the "dit, an "on" sigthe pulses has been rounded off nal lasting a given length of time too much to remove "clicks" and in seconds. For example, a 100 the signals sound mushy. At baud rate of signaling means that higher speeds, perhaps the dits are there are ten basic telegraphic too heavy and confusing the ear. elements per second (or 5 cps or These are things which the sender Hertz), and each element lasts may be able to modify on the 1/100 of a second, the reciprocal of the baud rate. Obviously, to perceive a dit or a dah requires silence both before and after it. The minimum element of silence

(space) is also equal to one dit. A square wave frequency related One dit followed by one element to words-per-minute, and the duof space constitutes a square wave two telegraphic elements long and may be called one "cycle," by analogy with a cycle of sinusoidal wave. (This is expressed symbolically in Chapter 28 by "1Ø".) A continuous series of dits would then for a given length of time have twice as many bauds as cycles per second. A sequence of 25 dits and (1Ø1Ø1Ø1Ø..., 5Ø elements) in example, assumed to be sent in one second would thus corre- one second, it will be at the rate of spond to a frequency of 25 Hertz, 5Ø 5Ø bauds. It is in this sense that (cps!square wave equivalent). For we compare these two frequencies this example there will then be 600 (audio frequency and telegraphic keying frequency).

For a filter the two predominant factors for intelligibility are pass band width and center frequency of the beat note. (The actual shape of the filter's frequencyamplitude response curve is also of importance but for other rea- Now to determine the minimum sons: see Chapter 24 and engi- audio frequency needed to fill in neering manuals.)

There must be enough audio cycles to fill in the keying pulse shape of the smallest code element, the dit, in such a way that all code elements begin and end clearly and are therefore properly timed. That means that the audio center frequency (pitch of the beat note) must be high enough to preserve the square wave shape closely. A mathematical (Fourier) analysis shows that the center audio frequency needs to be about 7 times the telegraphic cycle rate to give the best shape of So, we merely multiply the baud telegraphic pulses.

ration of one telegraphic unit can be worked out for English using the data in Chapter 28 as follows:-

For standard English text, there are 49.38 elements per word. This is only 1% less than the standard 5Ø elements used as today's standard word, so we shall use the $5\emptyset$ element standard here.

spaces If this 5Ø element word is, for bauds, or 25 Hertz, words in one minute -- 6Ø wpm, a high speed. Using this to convert wpm to bauds we multiply (wpm) by $6\emptyset/5\emptyset$, that is by 1.2. Since the duration of one basic telegraphic element is the reciprocal of the baud rate, in this case it will be 1/5Ø second.

> the telegraphic square wave shape well and give really high quality audio code signals, the following factors must be taken into account:

- At least two samples per cycle of audio frequency are needed to identify a frequency, (this factor of 2 for samples per cycle is cancelled out by the cps = _ baud rate). and
- Up to the 7th harmonic is needed for high quality.

rate by 7, the highest harmonic number.

this means an audio frequency of erators. $5\emptyset \times 7 = 35\emptyset \text{ Hertz for best Thus:}$ quality of code pulses. Thus it can be seen that, except for extremely high speed transmissions, there will be no problem, since the typical values of beat frequency are in the 400 - 1000 Hz. range.

The minimum bandwidth will be concerned with signal stability and intelligibility limits. If the bandwidth is too narrow the signal may drift out and be hard to find again. If it is too wide the risk of random noise and interfering signals increases. The rise-fall time of a filter to square wave input should not exceed about half a dit length. Working through the arithmetic for 6 dB down shows that the minimum bandwidth for Standard English should not be less than about 1.33 x (wpm). This is well below the bandwidth needed for signal stability, so there is no problem here for normal CW use.

Finally, if your copy doesn't seem to make good sense, and there is no way to verify it, see the end of Chapter 8 "Copying" for suggestions.

Signal required for CW with 5% character errors is 2Ø dB below that of double-sideband a.m. A good operator with CW at 15 wpm in presence of thermal noise, a 17 dB below double-sideband keying speed in bauds for good AM for CW was chosen to ac-

For our 6Ø wpm example above, count for differences between op-

CW - needs at Ø dB

compare with SSB - needs at +14dB (room for improvement)

DSB - needs at +17 dB (5 dB Difference in operators!)

Chapter 24

Bandwidths and Key Clicks

As discussed in Chapter 23, keying is usually expressed in bauds rather than in Hertz, or cycles per second. One Baud is one keying element per second, so one square wave keying cycle per second equals two Bauds. Using the standard word as 5Ø units, then (wpm) / 1.2 = Bauds. (Since 6Ø) seconds divided by $5\emptyset$ units = 1.2)

Harmonic analysis of the on-off keying wave shows that strong odd-numbered harmonics and weak even-numbered harmonics are present. It has been found that under good conditions, adequate readability results when the 3 harmonic is present, but under poor conditions we need up through the 5 harmonic. (Really signal to noise ratio (in one kHz good quality, however, will inbandwidth) of -1 dB is required clude up through the 7" harfor 10% character errors and +1 monic.) International regulations dB for 1% character errors. This have specified accordingly that latter is 22 dB below double side- minimum acceptable bandwidths band order-wire quality. However, should be at least three times the

conditions and five times for poor conditions.

Thus, working from standard Code Courses and Devices wpm, convert to Bauds by divid- Advertised in the Older ing by 1.2, then multiply by the Days highest harmonic (3, 5, or 7) desired. (Since this modulates the carrier frequency, the transmitted bandwidth will be twice this value because of sum and difference frequencies.) Accordingly, e.g., for 2Ø wpm, covering the 3rd harmonic requires a 5Ø Hz. bandwidth filter; for the 5th harmonic coverage a 83.3 Hz. bandwidth filter.

A perfect square wave will generate strong transient over travel, both!initially and at the end of each pulse. These spikes are especially objectionable, as they genwill interfere with other transmissions. For the receiving operator they produce an unpleasantly harsh quality. Shaping to round off these sharp corners of the wave by making a 5 - 7 millisecond delay gives satisfactory reception, but if it is lengthened too much it tends to blur the signals and make them hard to read. This situation can be taken care of only at the transmitter, of course. It can be seen that there is a delicate balance between "good quality" and troublesome harmonics. Refer to the handbooks for corrective measures.

Chapter 25

Dates show what I have been able to find

These items are in partial supplement to chapter 25.

Morse's first "sender" used tooth-like raised characters on a straight edge "ruler," over which a follower-contactor was pulled along in order to send. No doubt derived from this idea Morse (in 1844) is thought to have built a "transmitting plate," a board of insulating material having the code characters composed of metal bits imbedded in it. They erate a host of harmonics which were arranged so as to produce the code character (whose name was marked beside it) when a metal stylus was dragged!across the surface at an constant speed. (Such a plate was independently designed in Germany about 185Ø.)

> Telegraph teachers realized early in the game that the student needs a lot of practice hearing good quality sending. The transmitting plate may have become the earliest self-teaching device. (Such boards were advertised as late as 196Ø)

The Omnigraph

The Omnigraph, which first came out in 19Ø1, was an obvious derivative of original Morse "sender" with its raised "teeth." It was a mechanical device consisting of a hand crank, clockwork

characters past a follower-keying qualify an operator.) The govup together on a spindle-carrier used Omnigraphs to administer disks looked like a cylinder with until 193Ø, when I was tested. little "bumps" on it. A wide range of speeds from about 5 to over 6Ø wpm was provided for by adjustment of the brake on a fly ball governor which held the speed constant after it was set.

groups.

These machines were to be used with a sounder for American Morse or a buzzer or oscillator for International Morse. They seem to have had a very wide usage for basic learning and developing speed among would-be op-

or electric motor to drive an as- erators, including amateurs. (Adsembly of thin interchangeable vertising often claimed that a metal disks bearing the code month of serious study could device. Teleplex Co., New York City. First ad in QST seen Apr. 1927:

"The Easy Way to Learn the Code Cuts Learning Time in Half. The famous Teleplex for selfinstruction at home. The quickest, easiest and most economical way of learning Morse or Continental... Faithfully reproduces actual sending of expert operators.' Next month's ad: "At last! The Famous Teleplex ... with only a screw to turn.... 5 to 8Ø words per

was a large 5/8 column ad. The minute." Third month: "Learn usual later ad was about one inch the Code at Home This Easy Way larger. Price at first was \$3.000 for They provided a code instruction small booklet. These ads appeared manual and help and advice perfor many years afterward. (This is sonally by correspondence. It was the worthless "Eat Another Raw initially a spring-driven punched Lemon" method mentioned in paper tape machine. Later models were electric-motor driven. In 1942 they produced a paper tape model which could record one's own sending (using electrochemical means) as well as send user-prepared tapes. In 1956 they reverted to punched tape again, and in 1959 they went to a machine resembling the Omnigraph. Prices never published in ads. The Teleplex Company later brought Playback was by a pair of springcircuit. Later designs used a photocell instead of direct electrical contact for reading the tapes. This permitted the use of nonconducting inks. These differed only in degree from Morse's original "recorder." McElroy's company also manufactured this type of recording system. These types of systems were generally far beyond the average ham's pocketbook.

> The Candler System, Chicago. First ad seen in QST dated Sep.

one inch in a column. Price not limited. advertised. See Chapter 3Ø.

197Ø ARRL Handbook.

Øther devices included machines for producing code practice using punched paper tapes. The tapes were wound on reels and pulled by a clockwork-type spring motor or electric motor having adjustable speeds. The tape perforations actuated a spring-loaded contactor to open and close the circuit. Commercial machines were in use An odd little unit offered in 197Ø long before they entered the was called the "Cotutor." Similar to the Teleplex punched that you'll be copying that very paper tape machine, speeds from first day, words and sentences at 3 to 40 wpm. Last ads seen in the character rate of 20 wpm. Ted has taken one-half the alphabet and prepared a practice tape which runs for a full hour without attention at 2Ø wpm. You won't copy 2\Omega full words in one minute, but each letter you write will hit your ears at a full 20 wpm rate, and the space between the letters becomes progressively shorter as the rolls go along."

amateur field. There, Teleplex just a simple whistle with a set of earliest and best known; other bet and numbers. Each disk had Telegraph Keyer Corp., Gardiner so that the characters would sound

The real turning point in availability and variety arrived with the advent first of the wire recorder and then of the tape recorders. Some of these units could be Here, like the phonograph, the rented as well as purchased out- "machine" was probably someplayed over and over as desired. by ear. Many good courses became available and more are available today.

Some electronic keyboards and Speed Contests keyers offer a wide variety of preprogrammed practice materials for practice. One of their main advantages is that they always produce perfectly formed characters - something that greatly expedites initial learning.

But personal computers, which entered the scene actively in the early 1980's, offer the widest range for basic code learning and for advancing in skill. A wide variety of freeware programs for learning and for practice are available, as well as programs commercially produced. Not a few PC programmers have been able to prepare their own programs tailored to their own particular needs. A number of interactive programs are available which give either immediate or delayed helps to the student these offer tremendous help in learning. Some may also allow the more advanced student to conduct QSO's with the computer program, just as if he was actually on the air. The potential here is great indeed. (See Chapter 16)

Finally, there are available computer programs and devices which can read receive code transmissions. Because they are machines, they can only read code signals

thing already owned and could be which are reasonably accurate in used for other things besides timing. For the student who has code-learning. This kept the cost access to one of these, it will give down. Many prepared code tapes him a chance to test his own became commercially available, sending for accuracy. However, or could be self-recorded from they are not recommended as the radio or other sources and substitutes for personal receiving

Chapter 26

Speed contests - officially and unofficially - have been held over almost the whole history of telegraphy in America. Both the professionals and the amateurs have had a pride of accomplishment which begged competition to display and reward. Speed contests provided that.

After WWI speed contests among amateurs, but open to others also, began under the sponsorship of the ARRL and also local hamfests and amateur clubs. Ted McElroy, who was not an amateur, stood out as the world's speed champion for decades beginning in 1922. (In 1933 he lost out to Joseph W. Chaplin, but regained the title again in 1935.) There were others who demonstrated almost equal ability, and McElroy himself said on occasion that there were probably many others who were as good or better than he. Several unofficial records have been established in this country, and lately the European clubs have reported some astounding highspeed champions.

At first, in the latter 18ØØ's, contests seem to have been concerned only about sending ability. This implies that receiving ability ited by their sending ability only. miliar taped material, followed then machine sending entered so The test tape material was in plain could be achieved, do receiving newspapers and carefully edited contests seem to have become im- so as to contain no difficult or portant. Coggeshall, to be run in two heats. one of the four judges. Mr. Coggeshall was a telegraph operator himself, and later a vice president of Western Union. He was the only non-amateur judge. (QST November 1933 p 3., personal correspondence with Mr. Coggeshall and comments from McElroy, etc.) From these materials the contest may be described as follows:-

It was an "open" championship for the world's speed title and cup. More than 25Ø contestants showed up, both amateurs and professionals. Silver trophies were to be awarded in eight classes, beginning at 8 wpm. The contest was run in two sections, the first a preliminary classification test on August 4, eliminating most contestants, and the final run-off the next day. The first section of test began at 8 wpm, then 1Ø, and at 5

> Mr Coggeshall's personal reactions to the tests are interesting:

"At 8 wpm you sit back and twiddle your thumbs, you yawn... At 15 you take up your pencil and leisurely jot the stuff down... At 2Ø you see the first signs of life. For a minute or two you sit back and copy, and then, on second thought, you hitch your chair forward a bit and straighten the paper. At 25 you quit 'laying behind; you decide to close the gap until you read about a word behind the sender. Not so bad, now. At 3\O the fun begins. You can read it all right, but the pencil seems to be getting a little sluggish - better make a grab for a 'mill' [typewriter]. At 35 you begin for the first time to think about errors:

'How many am I allowed on a 5-minute test run of this?' At 4Ø it gets hotter and very suddenly, too. The last 5 wpm have more mustard on them, it seems, than the first 3\,\textit{O}\. You are holding your own with many a crack commercial radio or telegraph operator now. You quit worrying about single wrong letters and start hoping you can put a typewritten line down without leaving a word out. At 45 the jig is up. You quit, but half a dozen of the champs go on.... At 5Ø wpm the dots and dashes get blurred and jumbled at 53 it is just a lot of static - no sense now in trying to hear anything. At 55 there is no change. Just as easy to read the QRN [static]...'

As each group reached its limit, the contestants left the test room. Finally, eight passed the test thus far. Between this test section and the final run-off a WU cable operator, J. C. Smyth, copied 5-letter solid cipher code correctly at 45 wpm, making all the other contestants look like amateurs, and thus putting their attitudes on a more nearly equal footing for the speed grind to follow.

The test tape for the final run-off had been prepared and sealed in New York in the presence of Inspector Manning of the Federal Radio Commission, and was opened by Inspector Hayes of the Chicago office at the scene of the contest.

The final run began at 4Ø wpm - then 45 - then 5Ø, 53, 54.1, 57.3 and 6l.6 wpm. (The machine ap-

parently could not be accurately preset at these speeds, and speed was determined afterward by word count and time elapsed.)

Rules of the contest allowed a maximum of 1% error for each 5-minute run. At 61.6 wpm all made more than 15 errors. At 57.3 (1432 characters or 286.7 5-letter words) Chaplin had 11 errors out of an allowable of 14, while at 54.1 wpm he had but 5 errors, and McElroy made 8 at this lower speed. Chaplin was declared the winner at 57.3, breaking McElroy's 11-year old record (1922) of 56.5 with one error on a 3-minute run.

From this we can see that the 5-letter word had been standard for some time, and is in fact representative of regular English. It is not difficult to compare this with the present 5Ø-unit standard word (as in "Paris") by using letter-frequency tables (such as used in cryptanalysis. See Chapter 25). From this it can be shown that a word count based on standard written English may be expected to come within about one percent of the present standard of 5Ø units per word.

Regarding speed contests in general, Lavon R. McDonald wrote in 194Ø: "About the speed tests, government count is used, that is five units to the word. Only plain newspaper English is used, everything having clear meaning, no trick stuff."

As for the well known 1939 speed contest, where McElroy was credited with winning at a speed of 75.2 wpm, McDonald wrote: "In the Asheville tournament, the

speed was practically the same for McElroy and myself. We both copied solid (press matter prepared by the FCC), but they sent some stuff at 77 wpm and I didn't Some Of The More Common get a good start on it. McElroy Abbreviations In CW Work made something that looked like copy, but pretty ragged looking, so they gave him 75.2, I guess it was. If only first class copy had been counted, it would have ANT ended a tie. McElroy and I have had about the same telegraph experience."

At the present time the Europeans BK appear to have exceeded our recorded contest speeds. In the 1991 International Amateur Radio Union high speed telegraphic CUL championship contest Oleg Buzubov UA4FBP copied 53Ø figures (numbers) per minute with CW only one error: that is 1\,\text{0}6 wpm, 8.83 figures per second! Amazing! (See Morsum Magnificat 22-4) However, the duration of these tests is stated to be one minute. This seems rather too short in itself or to be in any way directly comparable with the contests run in America. It seems doubtful that these speeds could be maintained for three to five minutes.

Some of the others who have achieved very high speed have been:

Eugene A. Hubbell, Wayland M. Groves, J. W. Champlin, J. B. Donnelly, V. S. Kearney, J. S. Carter, Carl G. Schaal (W4PEI), Frank E. Connolly, Wells E. Burton.

1000 Ave. Structure length 11.23 Ave. 9.07 9076

The letter frequency counts (left- 2Ø.3% longer than normal Engmost column) are taken from one lish word length.) of the common books on cryptanalysis, based on number of occurrences per thousand of normal English text material. Each character is analyzed ("structure") into units, 1 for minimum signal duration (one dit), 111 (three units duration) for a dah, and each equal unit of silence denoted by!Ø (zero). The required three units of silence separating each character is added (ØØØ) to each one below.

From the above, if we take five times the above average letter length and add the space required for word spacing (seven total or $\emptyset\emptyset\emptyset\emptyset\emptyset\emptyset\emptyset$) we arrive at the 1 - E; normal English word length as 5 x 9.076 + 4 = 49.38. This is just a bit less than 1% shorter than 5Ø 5 - A, N, S; units per standard word. (By contrast, a random five-letter group averages 6Ø.15 units. This is 9-B, F, G, K, L, V, W;

A similar analysis of numbers will show that the average length of a number is 17 units (minimum 12, maximum 22) or a group of five numbers takes about 1.78 times as long to transmit as a five letter word.

Comparing these calculations will show some of the reasons why receiving speeds vary with the kind of material being sent.

As a matter of interest, we list here the letters from the shortest to the longest by the number of units (less letter space) -- notice that all lengths are odd numbers:

- 3 I, T;
- 7 D, H, M, R, U;

11 - C, O, P, X, Z; 13 - J, Q, Y.

Foreign Adaptations Of The International Morse Code

If the same kind of calculations are carried out for several foreign languages, the following results national requirements for comare obtained for the average character length: (Frequency data These requirements were: from Secret and Urgent, Fletcher Pratt 1942 Tables II to IV, p. 253 – ff.)

German 8.64Ø,

French 8.694,

Spanish 8.286.

These range on the average from 5 - 9% shorter per character than in English. There seem little doubt that if the code were somewhat redesigned and adjusted to optimize it for English a reduction of about 5% could be made.

For the Original American Morse code

Mr. Ivan Coggeshall made an analysis of American Morse comparatively, using the same normal dah lengths and word spacings one unit shorter, and arrived at an average letter (frequency) length of 7.978 (as compared with 9.Ø76)!and average number length of 14. As noted in Chapter 16, American Morse timing is open to considerable variation

Chapter 29

The Koch Researches

The obviously extensive researches of Ludwig Koch, Psychologist at Die Technische from printed code charts.

Hochschule, Braunschweig, Germany, reported in Jan-Feb. 1936 (see Sources), seem to be virtually unknown outside of Germany. His goal was to discover the most efficient way to teach the Morse code to prospective radiotelegraph operators to meet the Intermercial radio operators.

- send 1ØØ words in five minutes,
- copy a 1ØØ word telegram in five minutes, and
- copy 125 words of ordinary text in five minutes, one word being reckoned as five letters

Koch's researches involved: determining what competent operators are doing, examining teaching methods in current use, then devising better methods, and testing them in actual classes. His conclusions and recommendations seem to be the earliest real research into how best to teach the Morse code. They agree on the whole with the best methods of today, and may offer some further ideas of value to us. They are summarized!here.

Tests To Determine What Competent Operators Are Doing

He ran three series of tests to determine how the code is comprehended and for this purpose used competent, activelyfour practicing radio telegraphers. Three of these operators had learned the code solely by sound, while the fourth was self-taught

Sending Tests

For the first test each operator was to send by regular hand key the series of ten letters b c v q f l h y z x at various speeds while monitoring his sending with a pair of headphones to satisfy himself as to its quality. Out of his sight and hearing a recording system made an accurate timed graphical record of his sending, so that the actual timing of signal and space durations could be examined in detail. He was instructed to send, using standard International Morse timing, at each of six different speeds ranging from about 2Ø to 8Ø characters per minute. Standard International Morse 12, was then used to compare their sending at all speeds.

Below about 1Ø wpm the only operator who closely conformed to standard timing was the one code. The three others deviated considerably from "standard" timing. At 5 wpm these deviations were appreciable:

- The dits were too short,
- The dahs tended to be longer than 3 times dit length, and
- The spaces between characters were too long.

perfectly equal to their lengths.

At successively higher speeds this situation changed slowly and somewhat irregularly until by

about 1Ø wpm character rate all four operators were forming fairly accurate patterns of sound (nearly to the International Standard), except that the letters themselves were somewhat faster and the spaces between letters were somewhat longer than standard. By about 12 wpm all sending had become quite consistent with the standard. (Only the well-known individual peculiarities of sending by hand were obvious. At 1Ø wpm and above these deviations were always very small.)

The three operators who had learned by sound obviously showed no real sense of sound patterning (Gestalt) at these very low speeds: no sense of unity, but timing, as described in Chapter rather just a series of separate elements strung together. Only by about 1Ø wpm were the code characters now felt to be entities of sound in themselves, patterns which were clear-cut in each opwho had visually learned the erator's mind, lno longer shattered elements, disjointed parts.

Receiving Tests

Test number One: - Each operator was to copy the 3Ø German Morse characters sent by a machine in perfect "standard" timing!at each of four different speeds over the same speed range as before.

At about 5 wpm these experi-However, spacing between the enced operators hardly recogcomponents of a letter was almost nized a single character correctly! dit At 7 wpm only 4\,\text{\text{9}\% to 6\,\text{\text{9}\% of}} the letters were correctly identified. At 1Ø wpm all operators were getting about 95% correct. By 12 wpm all of them correctly identified every character.

is interesting.

From these tests it was concluded that experienced operators recognize a code character by its overall acoustic pattern (Gestalt), and that this pattern stands out clearly only when sent at a minimum character speed of about 5Ø characters per minute. At lower speeds it is heard simply as a disjointed – series of signals. --!Koch concluded that these operators could recognize the too-slowly sent letters only when letter spacing was doubled, because this increased interval gave them time to integrate the sound and mentally speed it up to where they could recognize it. (A beginner would not have the skill to do this.)

The operator who had learned from a printed code chart apparently formed better proportioned characters at very low speeds because his visual mental picture was so strong. However, the price paid for this was that it limited his maximum speed of copying: he could barely meet the minimum requirements - a marginal operator. (See below.)

Analysis And Criticism Of Previous Teaching Methods

ing some sort of systematic arnumber and type of related elements, etc., in a visual form. The

Test Number Two - Here the student is required to memorize length of the spaces between the this as a mental picture before letters was doubled. This time the going any further. After that, the operators recognized almost all characters are sent to him in stanletters correctly at all speeds. That dard timing, at first very, very slowly. This means they are sent with long drawn out dits, dahs and spaces. The speed is then very gradually increased in tiny steps.

The faults with this system are:

- To begin by learning visual symbols creates a useless detour
- Slow sending destroys any unity, or coherent soundpatterning
- The disjointed signal doesn't meet our need for a sense of unity
- Learner can hardly help counting the dits and dahs
- The long spaces between letters distract his attention from listening by:
 - Encouraging him to think and try to put the shattered parts together to make sense of them, a shaped unity, (Gestalt), or
 - Guessing what may come next
- At each increase in speed everything sounds different, and he virtually has to start over again.

The "Analytic" Method intro- In short, the student is sidetracked duces the student to the code us- and severely penalized all the way along: needlessly translating from rangement, or chart, where the bits and pieces of sound to try to code characters are arranged by put it together into a meaningful whole, then converting that to visual form and then finally to the Analyzing these methods, two

The "Sound-Pattern" Method first introduces the Morse characters to the student at a character speed fast enough for them to be perceived as an acoustic unity (Gestalt), but with wide spaces between the characters. However, the student has usually already visually mastered a code table or is encouraged to do so as he learns.

Unfortunately, visual mental pictures are usually very much stronger and easier to recall than auditory sound patterns. Thus the student tends to convert the signal pattern he hears into the corresponding visual representation, break it into its component parts, and then finally into the letter. This complex action tends at least partially destroys the wholeness of the acoustic impression.

This series of actions is encouraged by the long pauses between characters, giving adequate time for thinking, speculation and the The remedy is obviously to elimianalytic method.

So this method tends to suffer about the same faults as the analytical method. Both generally lead directly to that troublesome plateau at around 1Ø wpm, where the distinct change in perception from bits and pieces to coherent unity of each signal occurs.

classes of errors can be seen:

- Errors which hinder the building of a sense of acoustic!unity
 - Detour through an optical symbol.
 - Disintegration of the acoustic form of the character.
- Errors which prevent going directly from acoustic!impression to the letter:
 - Thinking about the signal during long pauses.
 - Guessing what may come next.
 - Converting or translating from sound to visual and from visual to the letter
 - Converting or integrating into a total rhythm pattern.

cumbersome translation proc- nate all visual references and asesses. With increasing speeds the sociate the sound directly with the pause time becomes too short to letter, to send fast enough from go through all this, and so the the very beginning so that coherstudent gets stuck below or ent sound patterns are immediaround 100 wpm, just as with the ately sensed, and to eliminate non-normal spacing between letters.

Tests To Establish A Better **Teaching Method**

Character Speed For Initial Learning

The obvious goal was to meet the International requirements. The question is how best to get there.

the first using a 100 character qualities and lengths make sound rate per minute, or some lesser patterns stand out somewhat like speed? This experiment was tried. little melodies. This helps accen-For the average student it was tuate the differences between found that the demands on his sound patterns and simultaneconcentration were significantly ously promotes an immediate greater at 100 letters per minute sense of meaningful unity of the than at 12 letters per minute, especially as more and more new introduced. characters were (Above average students did well, however, at the higher initial speed.) But, of course, if one learns initially at some lower speed, speed is going to have to be increased to meet the requirements.

12 wpm was an optimal speed for ing stages, while he is being intromost people to begin learning. It duced to the rhythms and trying is far enough above the 1Ø wpm to get accustomed to them? It plateau to avoid it. Further tests showed that once the student had mastered all the code characters at 12 wpm, it was relatively easy for him to advance to 7Ø letters per minute, and by continuing to practice using the same principles, to advance fairly rapidly, step by step, to the required speeds. Thus 12 wpm beginning speed seemed well justified.

Can The Rhythm Patterns Be Enhanced

Koch observed that in the early done make this easier for him?

He observed that some teachers were speaking, or even almost singing, the sound patterns of code characters using the syllables

Would it be better to begin from "dit" and "dah", whose vowel acoustic patterns.

Could the use of two different pitches, one for dits and the other for dahs, make it easier for the new student to recognize the wholeness of the rhythmic pattern ("melody") of a code character, and make it easier to learn? Could it help reduce the stress caused by the intensity of his Various tests showed that about concentration in the early learnlooked worth a try.

He conducted two classes simultaneously to evaluate the merits of the two-tone approach. After the first lesson, at each stage the twotone group averaged two lesson periods ahead of the monotone group. (For the two-tone class the pitches were gradually merged into one by about mid-course.) Results:- the two-tone class in 24 sessions reached what took the monotone class 28 lessons to achieve. Total teaching time was 12 (two-tone) to 14 (monotone) stages of learning, the beginner hours. (With both groups there has to concentrate intensely to were the usual, occasional short catch the letter rhythm-patterns. Is plateaus, each lasting generally no there anything which could be more than one lesson period.) Conclusion: - this is a worthwhile improvement to help the begin-

What Letters Should Be **Taught First**

Distinguishing Between Similar Sounding Patterns

What characters should first be presented to the student? Although tests had shown that students can, in their first lesson, readily learn to distinguish similar patterns such as the series e-i-s-h, the degree of concentration required had a negative effect on them. Experience has shown that many sound patterns, as speeds rise, can be mistaken for similar sounding patterns, especially in regard to the number of dits which become pretty short at higher speeds: e.g., S and H, or U and V. The dah characters do not run this risk so much: e.g., W and J. In addition some beginners do experience temporary confusion between mirror image characters, such as B and V, D and U. Thus it seems best to begin with sound patterns which are distinctly and obviously different. In this way the student can learn more gradually to discriminate between smaller differences.

Letters that Tend to be **Troublesome**

program.

When To Introduce A New Character

His tests showed that it is safe to introduce a new character into the list only after the student knows thoroughly all the characters he has already studied. He set his working standard at a minimum of 90%: that is, not to introduce a new character until the students were getting at least 90% correct copy at any stage. This provided a good measure for comparison, and at the same time let the student evaluate his own progress. It is indeed interesting that the test classes showed that students learned new characters almost in exact proportion to the number of lesson periods (total hours). The experiments also showed that three to four new characters were about optimum for any one lesson period.

Should Practice Be By Groups Of Letters

The question he asked is this: should the student practice one group of characters until he knows them well, then work on a second group separately in the same way, and after that combine the groups?

Koch says these (for German stu- He began this teaching test with dents) are generally x y p q. (Z is characters composed of dahs very frequent in German.) If these only: t m o ch (German single are introduced during the first character ch). After enough practhird of the program, there is tice (a couple of class sessions) to more opportunity to give them "master" this group of letters, he adequate practice, and this gener- began teaching the dit group e i s ally results in shortening the total h by itself in the same way. Next he combined these two groups together, and found that somehow during the intensive study of the second group, the students had

forgotten the first group almost ual characters, tending to miss or completely, and their confidence confuse them. They show up as was badly shaken. He had to be- little plateaus on his record of adgin all over again teaching these vancement. What letters these are eight letters together until they varies greatly from student to stuwere mastered together.

After this, when these eight letters had been practiced to the point where they were correctly and consistently identified, two new groups were studied separately in **How Long Should Lessons** the same way as the first two groups. First the group d b g, then after that the group u v w. Next, when these two new groups were mixed together, it was found that the d b g group had been forgotten. But worse, after these two groups had been re-learned together (d b g u v w) to the point of correct identification, and then combined with the first 8 letters, alas, the (combined) first two groups of 8 letters had been virtually forgotten!

It appears that the student's intense concentration upon a new group of characters by itself causes that group to override and tive. That is, spread out the lessons replace what had been previously "learned". He sensibly concluded that teaching by groups is wrong-headed. Therefore, the most efficient way is to introduce one new letter at a time and then immediately integrate it into the group of letters already learned, until finally the whole alphabet is complete. In this way all the previously learned characters are under constant review and repeated frequently without lapses.

Troublesome Characters

Experience has shown that quite a few students have some trouble identifying one or more individdent. The five-column copying forms described below serve to help identify which these troublesome ones are - needing more practice.

Be And How Distributed In Time

He cited B. Jost's researches which found that people learn more quickly and retain it longer for a given total learning time, when the lesson periods are shorter and widely separated in time. E.g., for a total of 24 lesson periods (which always include reviews):- to schedule four lesson periods a day for six days is four times more effective than to schedule eight lesson periods a day for 3 days, and that to schedule two lesson periods a day for 12 days is eight times more effecin time.

What is the ideal length of a lesson period? -- Koch found by testing that to have a long morning lesson, and then after corresponding length of rest period to continue in the afternoon, demanded too much intense concentration. The students got tired too quickly and the repetition practice was not as effective as it should be. By trial he determined that a half-hour lesson period was about optimum. (Even a 45 minute period began to show diminishing returns.) He finally recommended two half-hour periods,

one in morning and one in the afternoon as optimum.

Several courses using various of these principles were conducted. However, at the time of this report, he had not had classes where he could combine all the optimum test conditions. The students savable were people who were interested, but not primarily, at least, for professional purposes. Furthermore, they were employed at full-time work during the day, and were often tired by class time, which had to be scheduled in the evenings. Also, he could schedule only two or three half-hour lesson periods per week. Hardly ideal.

In spite of this progress was good, and no difficulties were encountered. Three to five characters were presented and learned in the first half-hour period. He aimed for many repetitions during each lesson, never less than ten repetitions of each character during a given lesson period, even after the entire alphabet had been introduced. Each successive period began with a lively review of what had been learned up to that point.

New Philosophy For Teaching

- It is a mistake to let the student see a code character in any kind of visual form, because a visual impression is so strong that it will almost invariably lead to analyzing it into dits and dahs, and thus shatter its unity.
- Each Morse code character must retain its unitary nature, its acoustic wholeness

at all times. This is facilitated by:

- Sending at a speed of at least 12 wpm (6Ø letters/minute) from the very first. This will promote the sense of acoustic unity and bypass the discouraging 1Ø wpm plateau (transition) region completely.
 - Emphasizing the melodic nature of the code patterns initially, like a little tune, by the use one pitch for the dits and a slightly different pitch for the dahs. These pitches are then gradually to be brought closer gether so that by about the mid-point of the program they identical and continue from there on as a single pitch.

From the very first all practice is to be in five-letter groups, with normal spacing between the letters, as in ciphered texts, but with distinctly longer pauses between groups. This has a dual purpose:

- To leave no time for conscious thinking or translation between letters, and thus to require direct passage from sound pattern to the letter itself, and
- So that the student will immediately become

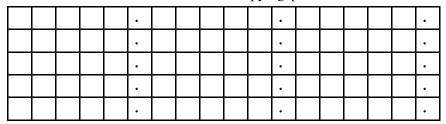

used to hearing letters in groupings as in normal communication, and not as isolated letters.

Designing An Efficient Teaching Program

The first exercise is to teach the student to hear and begin to become accustomed to hearing the different overall rhythms of sound and silence:-

- a. Character rhythm: Character - space character - space
- b. Group rhythm: Lettergroup - space - Lettergroup - space ...

From the very first, to get the student accustomed to overall rhythms, he is supplied with "copying" sheets having several sets of five-column groups of little squares like graph paper, as shown below. They will also be used for all subsequent regular copying practice.

Five letter random groups are b. then to be sent. At first these will all be unknown letters. As he hears each acoustic pattern of a letter in a five-letter group, he is to place a dot in the square which corresponds to the position of that A relatively short initial session sound pattern within its group.

Thus he works along across the five-space line, becoming used to hearing each letter-rhythm pattern and then writing a dot for it in the 2. appropriate square. (At this stage he only recognizes the sound patterns as entities, nothing more.) He continues to work line by line down the column as each new group is heard. In this way he begins the practice of focusing:

On the coherent acoustic forms and

- On the associated rhythm, letter by letter, of the writing hand, and
- On recognizing the pause after each group.

(1Ø minutes or so) of this will begin to accustom him to these overall and detail patterns of sound as entities.

- The second exercise is to start him on the way
 - To recognize the differences in rhythmpattern between two differentquite sounding letters, and
 - Become familiar with the sound patterns of

each character, and to become accustomed to them. (all sending to be machine precise.)

- This begins by introducing the two first characters just as sound patterns - without identifying what letters they are. They are to be sent separately and at random until the student definitely recognizes and distinguishes their individual patterns (pattern one and pattern two, or whatever). At this time they are not yet to be identified with their printed letters: they are simply recognized as different patterns of sound.
- Only after he has become accustomed to distinguishing the first two letter patterns from each other, and to the rhythm groups as they are, and writing dots in the little squares, is he to be told the names of these first two characters. He should from then on have no difficulty in writing their letters down in the little squares whenever and as he hears them.

This is to train him during these early stages and later on that he is to recognize and react to the pres- After one or two short (about 100) pattern, either by identifying it or larger groupings of letters identified by the longer space.

It is obvious that, especially in the learning stages, there are going to be acoustic patterns passing by which he may or will not be able

to recognize immediately and automatically. He must get accustomed to giving such signals no thought at all (except to put down a dot), so that he can give his undistracted attention to the next incoming sound pattern.

Otherwise, during the all-too-short pause after each signal which he does not immediately identify and before the next one is heard, he is going to try to think about what signal it was. But while he is thinking about it the next signal arrives, tending to upset him and cause him to lose the flow of the rhythm. This interruption must from the very first be stopped. His teacher must insist that whenever the student does not immediately and automatically recognize a sound pattern, just to put a dot in the corresponding square, then immediately let it go, and continue on with the rhythm. This action must become habitual, and this technique has been devised to develop it from the very first.

Now as he identifies the acoustic patterns he will write their corresponding letters in the little squares. If the teacher chooses to mix into the 5-letter groups code characters which the student has not been taught, there should be dots to correspond with them.

ence of each and every acoustic min.) practice periods this way, the relationships between the by a dot in the square, and of the acoustic impression and the letters they represent should have become so closely knit together that there is an immediate transition from the acoustic sound pattern to the letter (or a dot). Only when

ter to be added to the first two.

Only one new letter at a time is to be introduced and added to those already known. The criterion for adding a new letter is: when at least 90% of the letters already well known are correctly identified. Each new letter is added to the group of recognized sound patterns in the same way as the first two were: first by simple recognition of the pattern without knowing what letter it is, and in contrast with the previously known ones, and only when he readily recognizes it its individual sound pattern is he to be told what letter it is.

As an example of the introduction leave no time for conscious of characters and the five-letter thinking or translation between groups used, if the sequence of letters). I think if he had permitletters taught were h - f - a - g - ted or understood "Farnsworth" etc.: for the initial two-character spacing he would have been wise, lesson, groups were like:

- hfhhf fhfhfh 1.
- character: 2... Next aahfh fahfh
- Next: ggbaf ghfah
- 4. Next: ccgaf gcafh,
- etc. (In this example he did not begin with the more frequently "troublesome" letters.)

Summary

"It strikes me that Koch was allotted too little finances and was pressed too hard to get it out. Koch worked under several diffi-

this point is reached is a third let- culties. First, he had only 4 regular operators to study -- that's pitifully few as a sample, but barely enough (because he had been an operator himself) to draw solid conclusions.) Koch had very few classes to teach, and most students were only somewhat interested. None planned to enter telegraphy as a profession or hobby no amateurs were participating. Most or all had put in a full workday before coming to class in the evenings. He did not get to try combined techniques, but could only surmise they would function together.

> This semi-translation takes these factors into account and makes some effort to summarize them.

> Koch used 12 WPM character speed and standard character and word spacing, (his purpose was to based on the US experience. Subsequent practice would shorten these extra spaces as faster character recognition was achieved.

> With just normal spacing, the characters just come too fast for easy initial recognition, and so he could not use much faster basic character speeds than 12 wpm or many students would have become discouraged. Personally I believe that 15 wpm should be the bare minimum initial character speed and that 25 wpm may be too fast for some people until pattern recognition becomes obvious.

Koch's first concern was, the student has to get familiar with the code-type of rhythm patterns, and The Candler System he can only do this when the characters stand out alone clearly and are unitary in nature (not a jumble of dits and dahs in series).

The wholeness of each character pattern is vital. Musicians seem to do this more quickly and easily than non-musicians, who may need to learn it. N1IRZ Dave Finley has said this well in his book "Morse Code: Breaking the Barrier". Koch seems to have had little appreciation for the value of the so-called Farnsworth (spacing) method, where characters are sent at higher speeds than overall words per minute actual count. At one point he barely mentions extra word spaces. Nor does Koch recognize the value of starting the learner on longer characters (such as Q Y 1 5, etc., rather than on short characters and groups as E I T A N so as to learn early to hear out the whole character before identifying it.

It is this very first stage of learning that is so vital. Unless each character is so thoroughly learned by "reflex action" (stimulusresponse) practice that immediately after its sound (e.g., "dadidadit") stops it is instantly recognized as the character "C" the learning process is incomplete. Any attempt to build up speed is going to fail, and the joy of using the code is going to be diminished or lost.

Chapter 3Ø

No treatise on learning the code would be complete without a summary and discussion of this famous and formerly long-advertised course.

Background

By 19Ø4 Walter H. Candler had learned the American Morse code and worked for two years as a telegrapher. He had practiced diligently and felt qualified to apply for a job as commercial relay operator in the Western Union office at Atlanta GA. But he didn't last out there even one day, and had to take a night shift job as telegraph operator at a small town R.R. station. He was deeply hurt and puzzled. What was the matter? What mysterious ingredient was missing?

As was the custom at the best telegraph schools, he had visually memorized the Morse code from a printed table of dots and dashes, and then practiced and practiced. (This "standard" procedure was confirmed by a former teacher at the well-known Dodge's Institute no connection to the later C. K. Dodge "Radio Shortkut".) One night on the job, quite by accident, he discovered that when once in a while he dozed off at the operating table, he could read the fastest code coming over the lines to his sounder. Yet when he was awake and alert he could catch only a word here and there.

It was then that he began to realize that telegraphy is primarily a

mental process, and that the so- 1939, and made extensive notes called "sub-conscious mind" must play a vital part in it. (At that time here was quite a bit of popular writing about the "subconscious mind," which no doubt helped him put it all together.) He began experimenting until he had solved his own problem and mastered the code himself, and in time he became qualified to teach others how to do it, too. By 1911 he had established his own "school" in Chicago to teach "The Candler System," later moving it to Asheville, NC.

Although he died on 23 April 1Ø4Ø, his wife, who was already an experienced telegrapher her- Since Candler was concerned with 1959.)

The Course

Originally his "High Speed" course was designed for operators offices. who already "knew" American Morse, but were stuck at some too low speed. Later he added the International code to it, covering both codes. Still later a new course, called "The Scientific Code Course," designed to be successfully used by beginners working alone, was created from the regular "High Speed" course by modifying it to add helps to get the beginner started. (Thus it contained all that the "High Speed" course contained.) That new course was later renamed "The Junior Code Course," and was the one I obtained in October

on.

There is evidence that, although the essentials stood out strongly and firmly, over the years the details varied in minor ways. His basic philosophy may be stated as:- "This system trains you to use your mind" to develop "scientifically your coordination, concentration and confidence" your responsiveness. The course consisted of ten lessons plus considerable valuable supplementary material, mostly as letters. It is summarized below.

The Essential Principles

self when they were married in those training to become com-1924, and had worked with him mercial operators, he first emphasince, continued to handle the sized the importance of healthy course for a number of years. (It living: eating, exercise, breathing, was last advertised in QST in etc. This emphasis was needed in those days because the typical city operator worked long hours in unhealthy smoke-filled, darkish, crowded and poorly ventilated

> Develop "sound consciousness." -In Lesson 7 he wrote: "In learning code it is necessary to consciously count the dits and dahs of the various signals, both in sending and receiving. By repetition, the sub-conscious mind gradually assumes this burden of counting them. As long as you must consciously count them, work will be slow, but as the sub-mind takes them, they go faster and faster." "As you progress," he wrote elsewhere, "Begin to respond more readily to the

sound patterns than to visual ones: learn to shift from what you mentally see to what you hear. So long as you must consciously remind yourself that so many dits and dahs 'stand' for certain letters, you are not learning code." So, "when you hear didah, no longer say to yourself: 'didah stands for A.' Instead, when you hear didah, hear A. Do not translate." "In learning code you do not have to relearn words, but you do have to change the approach...from visual to auditory... Once you have mastered this consciously, your sub-mind will handle that detail, and do a faster, better job than your conscious mind possibly can."

Critique

We must remember that he and most of his students had already "learned" visually, and now this must be *replaced* by direct auditory recognition. Here was the real reason they all had gotten stuck at some slow speed. This traditional approach must have blinded his thinking so that it did not occur to him to *start the beginner with sound alone*, and so save the beginner from having to cross that annoying hurdle with its discouragement.

 Your sub-mind will only do what you have consciously trained it to do. Therefore, teach it the *right way* and the *same way* consistently from the beginning. Think

- and act positively: (The "I can do it" attitude). If you maintain a positive attitude as you think and consistently practice, the submind will take over the task more quickly, and it will become easier each time you do it. Conscious effort is needed until it becomes automatic. First you learn by consciously employing the principles in your regular daily practice. Then gradually, if you practice as directed, your sub-mind will take over the job with less and less conscious effort, and you will make good progress.
- 3. Learning to read code, to receive, is the important thing. That is, to understand without having to write it down. Reading means listening and understanding what is being said, just as in reading ordinary print or when listening to someone speak. Reading code must never depend on copying. As soon as you have learned all the letters, start listening to good code on your receiver (or nowadays, practice tapes, etc.) for 5, 1Ø, 15 minutes at a time, or until you become tired even if you cannot put together enough consecutive signals to form!words. Keep on, and soon you will be catching small words and then larger ones. But do not practice too long at one time - never when fatigued. "I am acquiring the ability

- to read words subconsciously now. When reading code, I know, as soon as a word is sent, what the word is, although I didn't consciously spell it out to myself as it was coming in,"!wrote a student.
- you cannot write down what you cannot read (receive). This is step two after learning to receive. Writing down what you receive is a routine matter that will take care of itself if you are properly trained. Of course, in the initial stages of learning the alphabet and numbers, etc., you must copy letter by letter, slowly, just as you had to learn to read that way. After this stage, stop until: When you get so you can listen to code and read it at 15 to 25 wpm without copying, you must begin copying some at each practice period. Commence this way: each day copy for 1Ø - 15 minutes, striving to copy one or more signals behind, then spend a similar period just listening to good code without writing.
- 5. When you do copy, learn to copy behind. If you have been copying letter by letter you must begin systematically to overcome it, and the best way is to listen to good code and form the habit of reading it without copying. As you acquire the independent code reading habit, by daily practice, you will find it

- easier to drop behind a few signals without confusion or fear of losing out when you are copying. You must break the bad habit of copying letter by letter. Get in the habit of carrying the letters in your mind, forming them subconsciously into words and sentences, without writing them down. "When I found I could begin to read small words as easily by sound as by sight, I was delighted. I soon learned to read words 'in my head. After that, copying them by pencil was easy. Previously, I had been writing words down letter-by- letter: that was wrong!" wrote a student.
- 6. Practice Intelligently: In the right way, Daily, regularly, in short and well- spaced periods, purposefully. Never practice error. Practicing when tired is not efficient use of time. A good schedule is 3Ø minutes daily, 15 minutes in the morning and 15!minutes in the afternoon or evening. The time between practice periods is important - use it to prepare yourself to be receptive by cultivating a positive attitude toward yourself and what you are trying to do. the ten lessons With these statements of basic principles in mind, let us look at the lessons for the beginner. Note that each new group of code letters was presented in the old visual dots and dashes

manner, but the student was told to *think* of the letters in terms of dits and dahs as they sound. He seems to have anticipated that a typical student would take a week or two to complete each lesson.

Lesson One

Emphasis on sound units. The first group was E I S H, to be sent smoothly and in accurate, regular timing by the student with his key, saying the dits as he pounded them out. Candler recommended that two or more beginners work together so each could send to and receive from the other. As soon as he can recognize them easily and send them smoothly, he was to form words, such as "he, is, see, his, she." Next to take the letters T M O, and do the same way, saying the dahs as he sends them, and then to make small words using both sets of letters, as before. Lastly the letters: A N W G. Then practice small words, including as many of the 1ØØ most common words as can be formed from these eleven letters. At one period Candler either supplied or recommended the use of mechanical senders, such as the Teleplex, with his course for the student studying alone. This would provide an accurate timing sense as well as good hearing practice. With a machine or companion, he would be able to listen and, during this initial period, copy letter by letter as he heard each character.

Lesson Two

Emphasis again on thinking of the letters in terms of dits and dahs as they sound, not as they appear in dots and dashes. Groups of new letters to be learned the same way: D U V J B; R K L F; P X Z C Y Q. Words to be practiced included the rest of the shorter $1\emptyset\emptyset$ most common words. Emphasis on accuracy of timing, and that repetition builds habit (whether good or bad).

Lesson Three

Emphasis on knowing you are right, then going ahead and making it a habit by repetitive practice. Analysis of the letters in code, accuracy of signal, spacing and speed: precision. Get in the habit of instantly recognizing each and every letter when you hear it, without having to stop and think: automatic association of each signal with its letter. Also now learn the numbers and commonest punctuation. When you have learned the letters so that you do not have to "stop and think" of what character any combination of dits and dahs represents, begin listening to good code every day regularly without copying, even if only for 5 minutes at a time. (The radio was his favorite source of good code: commercial press and government stations were on 24 hours a day. Now we have ARRL code practice, tapes. etc.) Catch everything you can as you listen. You may not get much at first, but keep trying and you will soon begin to hear letters and words.

Lesson Four

Think of the code as being easy to learn. Trust your sub-mind to do its work. Review and practice, especially any characters you tend to miss or confuse, until they are automatic. Every character must stand on its own feet. Keep drilling on the 1ØØ most common words, both receiving and sending. Begin using the "twocolumn drill" where you set up two parallel columns of three or four letter words, each having the same number of letters; then go down the columns spelling the word in the first column out loud while simultaneously writing down the other. Then do the same, reversing the columns. (See Chapter 8, "Conquering Our Fears of Losing Out," third paragraph.) These are the first easy drills on learning to copy a word or two behind.

Lesson Five

Practice each letter and character until you know them all so well whether receiving or sending that you don't have to stop and think about them at all. Do the same with the 1ØØ most common words. Keep up the practice of the two-column exercise started in lesson 4, going on to words with a few more letters as you find it easier. This is to *help disengage* conscious attention from the proper functioning of the subconscious mind so that it can do its work unhindered. Learn to trust it by continuing this kind of practice until it becomes easy. This is a highly successful method of training to shift the effort from

conscious to automatic, that is, subconscious, making it a useful habit.

Lesson Six

Development of skill is developing coordination, where everything runs smoothly. It begins by constant practice listening to and sending consistently and perfectly formed code characters, learning to recognize each code signal instantly, learning to read it all easily, and when copying, to write it down in a uniform, simple style of handwriting. Watch for any step along the line where there is any hesitation or question, and practice to overcome that block. Give this your attention, and allow time for it to develop until it becomes automatic, habitual. This is the scientific way. Do some practice copying mixed five-letter groups, but do not write down any letters of a group until the whole group has been sent. Have wide enough spaces left between groups to allow you to write it down before the next group starts. (His emphasis throughout the course is on receiving and copying normal English, not ciphered groups.)

Lesson Seven

Emphasis on proper timing while sending. Start by sending a series of letter E's with wide spaces between them, first with six counts between letters, then gradually reducing the space to normal one letter space. Then do the same way with S, T, H, O, etc. (Here he discussed "counting" as given above under "1 - Sound Consciousness, Critique.")

Lesson Eight

A discussion of "glass arm," or This is actually an old procedure telegrapher's paralysis, and its prevention by certain exercises, relaxation and proper warm-up. Continuing practice of fundamentals.

Lesson Nine

Obstacles to progress listed as:

- Lack of practice,
- Thinking visually rather than by sound,
- Hesitation over poorly learned signals, causing loss of the following ones,
- Looking back over one's copy while copying,
- Negative attitudes. One must force oneself to copy behind by degrees, gradually.

Lesson Ten

Learning to carry words in your mind by continuing the copying come second nature.

Chapter 31

The So-Called Farnsworth or Spacing Method

This method (in which the spacing between letters and words is lengthened to facilitate recognition of character patterns and words in the early

learning stages) is obviously excellent.

used by many teachers long before Farnsworth, who popularized it. It appears that the first clear mention of this approach is by Thomas Edison, a highly skilled telegrapher himself in 19Ø2. He hit the nail on the head when he wrote as follows about his punched tape course called 'Audio Alphabets" (by Frederick J. Drake & Co.) for teaching the American Morse code: "It is not the speed at which a letter is sounded that perplexes the learner, but the rapid succession in which they follow each other."

A few students have felt temporary rhythm recognition problems with the way this method was used by some teachers as the speeds were increased by shortening the spaces, making the characters seem to run together. They may feel a bit frustrated, but this is easily avoidable.

This effect seems to be most nobehind practice. Learning to write ticeable when using a character rapidly and legibly as an aid to speed of around 13 wpm, and is receiving. Learning to copy on one of the reasons why it is recthe typewriter. (He had a separate ommended from the very begincourse specifically for this.) ning to use character speeds of 18 Learning by doing until it be- - 25 wpm. These higher character speeds also make it easier to concentrate on the character as a unity of sound, without the risk of counting or analyzing it as a collection of shorts and longs. (Of course, after learning the code, we need to get used to hearing it at various speeds, including those slower than our initial learning speed. One reason: operator's

speed.)

This method starts out by having the beginner hear each character means at least at a rate of 12 or more wpm), rather than as composed of dits and dahs. It accentuates this perception by separating the letters and words at first by wide spaces, giving the student time to recognize each one clearly and associate it with its printed letter, or number, etc., and then as the student progresses, gradually shortens the spaces to normal length. It has been confirmed by experiments in psychology which have proved that if a stimulus can pauses between them. be grasped as a single unit, a In Chapter 11 of "Radio Simpliwill take place at a rapid rate. And with respect to how this course handled it, he added: "The principal feature of the Audio Alphabets is the graduation in the intervals between the letters. By beginning with a record in which the characters are widely separated and then changing to others with less and less intervals, the student gradually reaches the one having normal telegraph spacing."

This spacing method is perhaps the most obvious and effective way of focusing a beginner's conscious attention on the Gestalt, or form, of each individual code form of letter. It makes the lettercharacters.

tests for license will be slow So this is actually an old procedure based upon the experience many teachers long before Russ Farnsworth (W6TTB), whose from the very first at a high name apparently became attached enough speed for it to be per- to it because of his Epsilon Received as a unit of sound (which cords Code Course consisting of 3 LP phonograph records in an album put out in 1959. In that course the characters were from the very first sent at 13 wpm, widely spaced, and the time between them gradually reduced as the student became more proficient. Next of record we find two bulletins published in 1917 and 1918 by the Federal Board of Education which recommended sending each character at a rate of 2Ø wpm with rather lengthy

wholeness or "Gestalt", learning *fied*", a popular book of 1922-3, authors Kendall and Koehler, instructor and director respectively at the YMCA Radio and Technical Schools in Philadelphia wrote about learning the Code: begin with, the novice should not set out by committing [to memory] the number and order of the dots and dashes in the various letters and figures in the code, as for example, that "dash-dot-dash-dot" equals "C". Much of the energy so spent will be wasted. The radio operator does not recognize letters as so many dots and so many dashes nor does he translate signals in that fashion. The operator hears and learns to recpatterns stand out prominently ognize each letter as a combinaand allows him time to associate it tion of sounds "dah-de-dah-de" with its equivalent printed letter [sic.] as the letter "C", "de-dahwith a minimum of interference de" as "R", "dah-de-dah" as and distraction from all other "K", etc., in much the same manner as children in the primary

school learn to read words by sounds instead of by learning to spell them."

Although they do not mention the spacing method directly, they imply it by comparing it to how children learned to read in those day, by recognizing letter forms Other languages require certain and spelling out words at first. This involved one at a time learning with spaces as a natural part of learning, without calling any special attention to it. 194Ø, in his Master's Thesis "Teaching Radio by Radio" Marshall Ensor summarized his highly successful code teaching methods (which began about 1929 from Olathe KS). He clearly used this spaced-learning method to teach hundreds of students during his one-hour lessons daily on 16Ø meter phone "broadcasts". Each lesson alternated teaching code, theory and regulations. (See Chapter 12)

In 1945 Ted McElroy offered printed copies of his free 'Morse" Code Course said to contain "everything he has learned in 3Ø years of operating experience." He claimed that, "Assuming that the average person will practice several hours the first day, we can tell you ... that you'll be copying that very first day, words and sentences at the rate of 2Ø wpm. ... You won't copy 2\empty full words in one minute. But each letter you write will hit your ears at a full 20 wpm and the space between letters becomes progressively shorter as the rolls go along

Chapter 32

Other Alphabets

This would be incomplete without some mention of non-English alphabets.

diacritical marks, or additional letters, or symbols for common digraphs (single sounds represented by two letters in writing, like our th). Here we shall include the Germanic group, French, Spanish, and Polish, Hungarian, Turkish, all of which use the Latin alphabet, and Greek, Russian, Hebrew and Arabic, which use different alphabets. Japanese does not have an alphabet, but uses a syllabary (spelling by syllables instead of single sounds), and requires 73 - 78 characters In general, letters which represent sounds more or less identical to those in English are represented by the same code signals as in English. For example, B, D, F, G (hard)*, K, L, M, N, P, R, S*, T. "A" represents the letter "A" in European languages, including Russian, and Alpha in Greek, Aleph in Hebrew and Alif in Arabic. "C" represents written "C' in European languages and Polish, but é in Greek, thf in Arabic, samech in Hebrew, and tseh in Russian. "E" represents "E" in European languages, Greek and both yeh and eh Russian, but vav in Hebrew, and hamza in Arabic. "G" represents ghain in Arabic, not jæm. "H" represents "H" in European languages, "H" Greek (a vowel), "X" in Russian, HeT in Hebrew and guttural Hf in Arabic. "I" represents the same

A Brief History of United States Operator Licensing Requirements and Military **Training**

In the Beginning

kind were required, either for sta-European languages, "hard" L in tions or for amateur operators. Polish, Xi in Greek, both tvyordy An amateur, however, might apply to the Navy Department which would issue a "Certificate of resents this letter in European Skill." This merely stated that the successful applicant was "proficient" in code. It had no legal

In 1912 Congress passed the first laws requiring licenses for wireless operators and stations whose sig-

Interfere with government or bonafide commercial stations (those open to public use) or

- b. Cross state lines.
- This meant that very, very many "Little" stations and their operators did not need licenses. "Little" often included even those up to one kilowatt, the maximum allowed for any licensed station. This was because the 'passive" (mostly crystal detector) receivers in those early days were so insensitive that reception over land masses beyond a hundred miles or so was exceptional. The word "amateur" does not appear in these regulations, but is covered by the term "experimental". [In England, by contrast, a license was required even for owning receiving equipment.

From 1912 until 1933 operator and station licenses were sepaidentical requirements. In Aug. serious interference

1919 the required speed was raised to 1Ø wpm.

When the U.S. entered WW-I all radio activity, receiving as well as transmitting, except for that specifically authorized by the Military, was prohibited. All equipment (including all antennas) had to be either dismantled or sealed. This began on 17 April 1917 and continued until 12 April 1919 when receiving was once again permitted, and finally when amateur transmitting was again allowed on 1 October 1919. 1923:a new Extra First Grade was created requiring at least two years experience as a licensed operator.

A new written examination included requiring the applicant to diagram a transmitter and receiver and to explain the principles of their operation, plus a code speed test at 2Ø wpm (the speed required of a Commercial First rately issued and were impressive Class operator). The license was diploma-like documents about 8 printed on pink paper! Such opby 11 inches. They had to be erators were qualified for "Speposted at the station location and cial" station licenses which conwere usually framed by the op- veyed CW privileges on certain erator. Initially there were two wavelengths longer that 200 meclasses of license, with identical ters and also gave them distinctive qualifications. Amateur First call signs. As shorter wavelengths Grade was by examination by a came to be used this grade of ligovernment examiner covering: cense lost popularity. In the early radio laws, regulations, proper 1920's licensed amateurs began adjustment and operation of to get skittish about working unliequipment, along with sending censed stations (with their selfand receiving tests at 5 wpm in assigned calls), including the "lit-International Morse code. For the boys with spark coils." (They those living too far away to come were often a big annoyance and in for personal examination, there source of interference.) The Dewas an Amateur Second Grade partment of Commerce, howwhose applicant had to certify by ever,!seems to have taken little mail that he could meet these notice of them unless they caused

The newable. 1928:- "Special" li- Class B (general) examination censes reinstated on somewhat covered less on phone operation, different terms, and called "Extra and gave all privileges not re-First Class" operator. 1929:- the served for Class A, but required 2Ø meter band was opened to re-examination for renewal. Class phone, and Extra First Class li- C, a temporary license for those censes were extended by an en-living 125 or more miles from an dorsement "for unlimited radio- FRC examining point (administelephone privileges" on that tered by class A or B amateur), band. ?? 1932:- Extra First Class differed from Class B only in berenamed Class A, Amateur Class ing taken by mail. 1936 the code speed for all classes was raised

1951 And After

1951

The whole structure was revised for Amateur licenses: Extra Class (new, available 1 Ja. 1952), 2Ø wpm, no exclusive privileges, two years Advanced Class (previously Class A), 13 wpm General Class (Previously Class B) 13 wpm Conditional Class (previously Class C, by mail, 125 miles or more), 13 wpm Technician Class

(new, available 1 July 1951), 5 wpm, 5 years Novice Class (new), 5 wpm, one year, non-renewable

1952

Hams licensed before May 1917 eligible for Extra class without examination.

1953

No new Advanced Class to be issued.

1954

Novice and Technician available by mail only after 1Ø Jan., if over 75 miles from examination point.

1964

for new or renewal of license, except no feel for novice.

1967

Incentive licensing was adopted. Advanced class was reactivated and given more spectrum than General class, but less than Extra class. Novice class licenses were extended to two years.

1968

Advanced and Extra were made available for shut-ins, and Technician class eligible for Novice.

197Ø

Fees increased to \$9.\OO, five years license duration.

1976

Required new Technician class to be tested by FCC examiner.

1983

Volunteer Examiner (VE) system set up to conduct Technician and General class by December.

Various Military Training Requirements

At the outbreak of WW-I the U.S. Military forces desperately needed wireless operators and equipment. Many amateurs volunteered as operators and as teachers. Training in all phases was minimal, and "operators" were usually graduated without having had any hands-on experience with the actual equipment or operating procedures. (Absolute 17 Mar. filling fee \$4.\OO assessed radio silence was the rule in general - except for the most extreme emergencies on the high seas.)

> For operators in the WW-II period Signal Corps graduation requirements were: 25 wpm plain language, 2Ø wpm code groups with pencil or mill, receiving, and 25 wpm sending. Qualifications for field operators - 2Ø wpm pencil printing copy and perfect sending copy at 15 wpm; for fixed base operators - 35 wpm straight copy on mill.

For Marine Corps graduation they were: 2Ø-23 wpm plain text, 15-18 wpm coded groups, 17 wpm perfect sending of plain text. WWII training varied widely between various schools, but included actual operating procedures though wired QSO's among themselves to overcome the beginners' initial "buck fever" and to set them up as operators.

Real radio interference learning to copy through QRM and noise was the student progressed. Advanced same things. students also practiced on the "mill" (typewriter). For high Sending and writing at the same speed training, there was a room where high speed press was copied for practice.

In 1988 a U.S. Special Forces radio operator's test required!18 5character groups (e.g., QY9/Z 6G.J4 X5,B7, etc.) a minute.

Chapter 34

Examples which Illustrate the Nature of Real Skills

The following are samples taken from the literature to show various skills some operators have achieved.

They illustrate clearly the autoaction than before.

Receiving Code While Doing Something Else

Both in the past and in the present there are very many examples of sending or receiving while speaking or doing other things at the same time. Old land line op- One ship operator offshore of

added, and it became louder as hams today can and often do the

time

Almost all old Morse operators developed this kind of skill to some degree, and usually were able to send with one hand while writing on the message blank the number, time, date, etc., with the other hand. Pressure of work almost demanded it in a busy office.

Sending and receiving simultaneously

A regular RR agent-operator at a small town near Salina, KS, was observed to be sending a bunch of RR manifests (lists of freight cargo, giving details) when he was called on another wire. Without matic, subconscious nature of real pausing, he opened his key with skill in telegraphy, that it is a ha- the other hand, sent an acknowbitual form of behavior, done ledgement, closed the key switch, without conscious intervention or picked up a message blank and effort. They also show what can slipped it into the typewriter, be done by what has been done, rolled it into position and pro-People who do things well do not ceeded to copy the message with struggle with them: they enjoy one finger of his left hand while doing them. It can be seen that continuing to send the manifests there is a hierarchy of skill habits, with his right hand. This was not ranging from lower degrees to at all unusual for regular operavery high degrees of skill, each tors: there are many examples. A step leading to greater freedom of slightly different example is with the many old RR operators who regularly would copy down an incoming message with one hand and simultaneously send it on down the line with the other hand.

Receiving two or more messages at same time

erators typically could do this at California had the amusing expespeeds up to 35 to 4\infty wpm. Some rience of simultaneously receiving the identical message for him

KPH and KPJ. Both called him at afterward. That looks a little hard! go ahead, but instead, both began Morse International codes simulat once to transmit. He tried to taneously:copy them both. This became Johnstone of old KPH was a phevery easy when he discovered nomenal operator, said to be one they were both sending the same of the best of his day. He could message. The climax came later send one message in International when both of them billed him for Morse Boston Postal Telegraph office a hand in American Morse. Similar wire chief claimed he could si- claims have been made by others multaneously copy one message also. in French with one hand and another in English with the other hand. His chief operator took the challenge, promptly went out and picked up one message in each language, provided pencils and pads to the wire chief, and had the two messages sent to him simultaneously at the usual keying speeds. The wire chief made good on his word in the presence of all the other operators in the office, and made perfect copy on both.

A former Navy operator claimed that while copying one message, he often could mentally note other messages which were interfering with the reception of the one he was copying, and do so accurately enough to write them out later. He said that, especially when he was copying some particularly dull and uninteresting material, he was always fully conscious of the content of messages heard at the same time on adjacent frequencies concerning shore leave, pay or other interesting aspects of these transmissions.

One expert operator in San Francisco is credited with having received three separate dispatches at the same time, writing each of

from two different shore stations, them out correctly by memory same time, and he told the one to Using both American Morse and (Dick) Robert while simultaneously the same message! In 1924 in the sending another with his other

Comparison with other mental functions and discussion

Can't we compare this to a certain extent with other habitual activities, such as driving a car while thinking of something quite different? (Later wondering, e.g,, "Did I stop at. . . , or did I drive on?") Or like the stenographer who looked at her notes after taking dictation and was startled to see she had written a joke being told in the same office while she was taking dictation?

Doing two things at once, one subconscious or automatic and the other conscious is relatively commonplace. For example, I can read aloud from printed matter while consciously thinking about something quite different, and still read so that it sounds meaningful - yet afterwards have little or no recollection of what I had read aloud (and sometimes wondering if I had included anything of what I had been thinking at any point along the line.

As for the operators who could copy two messages simultaneously, is it possible that both ac-

hearing one with the right ear and tabular matter. Hand sending was writing it down with the left hand, absolutely steady, rhythmic and while hearing the other effectively even, intelligently coded and with the left ear and writing it with spaced - a joy to listen to. On the the right hand, or what? Or, was main traffic arteries of the Associthe one automatic and the other ated Press, speeds up into the 6Øconscious, although done at fairly 7Ø- wpm range were said not to high speed? If both were auto- be uncommon. In 1937 WCK had matic, were they free to think of two press schedules, one at about or hear something still different at 45 wpm to be copied by ear and the same time? For a human example, how does the traffic control officer of an airport keep alert to the arrival and departure of many aircraft all at the same time, seeming to give each "simultaneous" attention? Very interesting, isn't it?

Speeds

By 1933 it was written that a good commercial operator can and an 8-hour stretch, handling eve- because I don't remember trying

tions were automatic? Were they rything from straight news to

Jim Farrior W4FOK wrote this way:- "When I was a boy of 13 I lived in a small town in AL. The RR telegraph office was one of the few things in town that interested me. One of the three agent telegrahers gave me his sounder and telegraph key. The night agent usually had little work to do and often helped me by sending to me and telling me about operating procedures, etc. sounder there was nearly always active, and I gradually became able to copy directly from the wire. I guess I learned it pretty does average about 400 wpm over much like one learns to speak,

and dreamed that some day I winks of sleep.) might become a telegrapher."

Some Interesting Examples Of Young Skilled Operators Of The Past

O'Brian delivered telegrams for for his speed of 38 wpm (by achis brother Richard, who at age 15 tual word count). These are just was the telegrapher for the local two examples of the many, many RR office. After two years of this boys who quickly became skilled John prevailed upon his brother telegraphers in the mid-18ØØ's. to teach him how to operate. So, while still only nine years of age John became a good operator and was eager to have a job of his own. The RR offered him the position at a nearby town, and he snapped it up. People in those days were used to seeing young telegraphers, but not this young! Very soon, however, they became so pleased with his work that no more questions were asked.

Those youngsters were motivated and quick to learn. When the Civil War began he volunteered along with many others, became their youngest operator, and by early 1862 was already the assistant operator at the important military station of Ft. Monroe, VA, and considered an expert. When the Commander, General Wool, first saw him he was astounded. On a subsequent military assignment at Norfolk, VA, on one occasion John scrawled down two incoming messages while he was actually asleep, writing them down in a book he had been reading. (Civil War operators often worked impossibly long hours under diffi-

to learn. I was told that it was cult or dangerous battlefront conreally very easy, and I guess I be- ditions, and when things let up a lieved it. I was just having fun, bit, easily dropped off for a few

James H. Bunnell became an operator at age 13. He was so short that he had to sit on a stool to reach the telegraph instruments. At age 16 he was one of the best In 1856 seven year-old John operators in the country, noted

Examples Of Effective Code Learning

Learning

At the lowest skill levels: Fouryears-olds, barely able to write even block letters have been able to pass the code test. How many of us are willing to admit a fouryear-old can outperform us?

Then consider these higher skill levels:- In 19Ø9-191Ø Don C. Wallace learned the code with a friend, John Cook, and the help of the operators of Commercial station PJ in San Pedro CA. In 191Ø he set up his first station. In 1915 he passed the test for a first class commercial operator's license, said to have required demonstrating ability to handle 25 wpm in Continental code and 3Ø wpm in American Morse code. Later with Tony Gerhardt he played a game they called "burnout." One would send as fast as he could with speed key (bug) while the other copied on a typewriter, the idea being to see who could go the faster. This continued wherever they were until Don months later, and finally was could send in excess of 45 wpm given a job as sole operator on and receive about 55 wpm

second shift all summer.

Later he needed a staff of 35 assistant operators of about his own speed capabilities. Within a short time he found them among Navy personnel where he was stationed, and did it this way: by sending his requests at these speeds and seeing who responded to what he sent. Here were at least three dozen men with high speed skills before 192Ø. They were men who enjoyed the code so much they achieved high goals. Moral: If you want to do it, you probably can.

Arnie's Father was chief telegraph operator at a RR station and had once won a 6Ø wpm award in a contest for RR operators. His son, age 8, Arnie hung around the station all his spare time. He didn't say how, but he learned Morse on his own and soon had learned to send and receive at about 25 wpm. When dad was out he copied down the train orders for him. He wanted a job as operator. After much pleading, his dad said he could operate the station all by himself when he reached his 9th birthday. So he did, all day, while his dad looked over his shoulder and smiled a time or two. Arnie begged the RR to let him be a second shift operator after school and weekends for 5Ø cents an hour as second shift operator. He was required to pass the cookedup special qualifying test: of sending a train order at 25 wpm using one key with his left hand for the dashes and a second key with his right hand for the dots. He succeeded in doing it some

Appendix

A New Way To Talk

"It was in 1925 in eastern Pennsylvania that Ed Hart at age 15 became a ham with his first operator's license and call 3NF (two licenses were required in those "So my advice is: to acquire proso much fun with? Was it some to talk can learn CW. sort of new language he was usmy big brother Ed. He was my ideal. He was 15 and I was 11.

"I didn't start out with any determination to learn the code, or to get a ticket, or get on the air. But Talking one day -- it was 14 Sept. 1926 -using my brother's station, when I was 12, that I made my first QSO with W9CRJ in Lexington, KY,. I was pretty shaky on that first

contact and Ed had to finish it for

"When I was 14 I clocked myself at 34 wpm, plain language. I discovered that I had mastered the Morse code and was able to carry on a conversation just like Ed did.

days). His 3-1/2 year younger ficiency in code sit and listen, and brother George got curious. What keep listening and want to underwas this Ed was doing and having stand it. Anybody who's learned It's that easy. Just live with it and it will ing? -- George said:--"I admired come to you. Morse code is just another way of talking." [Youngsters and adults will no doubt begin to learn differently.]

Learning conversational CW is tening to my big brother operate more like learning to talk than it is to learning another language. It mosis' -- recognizing and imitat- is far easier -- you don't need to ing the more frequent sounds I learn how to pronounce or hear heard. I wasn't aware of any such strange new kinds of sounds, learn thing as "dots" and "dashes", a new vocabulary or a new grambut only of symbols with mean- mar. It is just recognizing the simple mono-tone sounds and I quickly learned the sounds of imitating them. Learning it is "all a matter of incentive."

such as "AR K", "DE" and speed CW is a natural progression, "R" (all still used), and "U" (for if you learn it right in the begin-US calls to foreigners before the ning and continue to practice it prefixes W and K were issued), the right ways." .For receiving and absorbed other sounds, as George has for many years been sounds with meaning. I just sort able to read code up to 600 wpm, of drifted into it by listening. It almost 7\,\text{Ø}, but now he can only send at about 4Ø, and so his QSO's today are rarely over that speed.

Most of us talk so fluently and so easily that we scarcely give a thought to how very different we are from every and all the animals. From birth we are well on

our way to learning to express our Now, what about Morse and other and loved. family and society around us -communicating first in body language and simple cries, and soon in the spoken language of family, friends and neighbours.

Behind "language", communication is this growing overall sense is our ability to think. Human thinking is a God-like activity. At first we tend to think of concrete things: things seen, felt, But tasted, smelled and heard. soon we begin to have thoughts of things not having physical existence, things we remember or imagine. We learn to think and This year, 2001 A. D., the solects.

Writing and learning to read are other skills, not "natural" or inpractice.

Written records of what was once just spoken have been kept for at least some $6\emptyset\emptyset\emptyset$ to $7\emptyset\emptyset\emptyset$ years. Strings of spoken sounds or syllables (Japanese, etc.), and sometimes whole words (e. g., Chinese) have been given arbitrary, but conventional symbols ("characters").. One such set of symbols has been generally agreed upon within each language group.

needs:-- for water, for food, to get telegraphic codes? Where do they rid of some discomfort, and for fit in? What are they? They are companionship, to be cared for more like writing than they are of To be part of the speaking. They are more like a different alphabet or (small) set of symbols than like a language itself.

> Many of us today are so literate that we read as easily and readily as we talk. We hardly see the one as being any different from the other.. We can think, and to express what we are thinking and communicate with those around us, we use our native language. .

> Let us here in this appendix rethink our views and our attitude toward the Morse code.

express our thoughts about these called Morse telegraph code "things' in words, too. Using simple stop-start, and different languages and dia- on-off type signals or motion, we can communicate using touch, sound, light, electricity, radio

herent or innate, but by practice It has no dialectical peculiarities, they seem almost automatic, as no lisps, no strange or difficult-totalking is. Learning to write and hear or pronounce sounds, or to read takes conscious effort on "speech defects", nothing to each one's part, and lots of active make it hard to understand... Paralysed persons can use it to "talk" by blinking the eye or wiggling a finger. More normal people can use it by radio to talk to those on the other side of the world or in space. With practice and the help of modern sending equipment it can be transmitted and "read" by ear at speeds almost as fast as ordinary conversation. It may be sent and received automatically at speeds many

terest to us here...

Edward Vail, one of Samuel Morse's hired and most valuable co-workers, did not realize what a wonderful communication tool he invented in 1838.

Let's keep these words in mind:- it is a communication tool.

In the early days of telegraphy it was thought of as "writing at a distance", which is what the word These are clues to help us speed telegraphy means. (See Ch. 19.) But very soon the early operators found they could understand the letters and words from the noises the printer made. Then they discovered they could also just converse together without having to write anything down. This all occurred within 1Ø - 15 years of the start of telegraphy. Talking by Morse code is not something new at all

How then did we radio amateurs get started thinking of it as something to have to learn to write down? It is because writing ernment amateur operator's li- copy. cense we had to be able to copy it at various specified speeds. (This is still true but at a speed which is #1 Theodore McElroy hardly practical - 5 words per minute.)

But do we copy down everything to think of that would seem silly.

We understand speech because it is spoken as strings of sounds one shifting or blending into the next, forming words and sentences. We

times faster, but this is not of in- learn to understand code the same way, but with a different form of characters, spelled out as words. In this way it resembles reading, because we need to know how to spell. This is an added (hopefully) small difficulty for English speakers languages. Spelling is hardly a problem for speakers of Italian or Spanish, which are spelled almost exactly as they are pronounced..

> up to near talking speeds. Now in the next chapter let's see how to go about it.

QRQ Operators

The experiences of a Number of **QRQ** Operators Who Have Achieved it

This is roughly in historical sequence --documentation of specific high-speed operators, mostly amateurs .:

I. Highest hand-sent code speeds in the range of 45-55 wpm using a bug.

it down exactly as it is heard is the As test speeds were achieved by only proof positive that we have commercial high-speed punchedcorrectly received it. This is called tape sending machines. The em-"copying? And to obtain an gov- phasis was the evidenced ability to

Reading did, not count.

Who was a commercial telegrapher, not a ham. Perhaps the earliest and most famous name at we hear on the telephone? Even high-speeds is Ted McElroy who almost permanently held the high-speed record of copying at 75+ wpm from 1939 wpm on. What many may not know is that at 75 wpm Ted acknowledged that cal winner.

Ted was born 1 Sep. 19Ø1 and died suddenly in Nov. 1963. He was one of four brothers who were telegraphers. He left school in 1916 and went to work for Western Union as a messenger boy. As he passed by the telegraphers, he saw how many of them could nonchalantly turn out 5Ø -6Ø messages per hour. He managed to get some of them to teach him Morse code during their 15 minute rest periods and after a few weeks he imagined that he In a telegram to Frank Borsody was himself to be a good operator.

He got a try-out - it was tough but it gave him a start. He found odd and ends jobs here and there and finally wound up at Fort Devons, near Ayer MA, where he continued until the end of the war in 1918.

International Morse code at stastation moved to NYC, but it didmoved back to Boston and got a job with WU again.

On 6 May 1922 he learned of an Exposition in Boston which would include a code speed contest. His In a telegram from Dorchester boss allowed him the evening off MA dated in 1935 to F Borsody,

there were many other operators to try, and he easily wound up -who had abilities as good or better using International Morse code, than his, but they did not enter the which by then he hadn't used for contest. What most people do not about a year -- at 51 wpm.. It was know is that Lavon N. McDonald great fun for him. Later in 1922 was equal with him, and but for a at Chicago he won the trophy at slip in the increase to 77 wpm 55-1/2 wpm with perfect copy for trial, might have been the techni- World's championship. He lost it to his friend Joe W. Chaplon at 55.3 wpm with 11 errors. In Sep. 1935 a contest at Brockton MA he retook the title. Again at the World's Fair he scored 69 wpm with only two errors, while Joe Chaplon made three. In July 1939 he and Lavon McDonald of Chicago tied at 75 wpm. But when the speed increased to 77 wpm McDonald fumbled worse than Ted did. So Ted was called winner at 75.2 wpm which has remained as the official world's record.

dated 14 Sept. 1933 he wrote "to my old pal Frank Barsody, in grateful recognition of the valuable coaching and assistance he gave me, to which I owe my ability to gain the world's championship as Radio Operator. And again in a letter dated 4 Sep. 1935 to Frank Borsody Ted wrote "You have been the best friend to Back in Boston he got a job using me on this code racket that I've got. I cannot understand how I tion RCA, Chatham MA. It was can fail to win it this year. As I sit rough getting used to the new in this chair I am copying solid (International Morse) code during (?) without a single error for five the first two weeks. In 1920 the or ten minutes at a time, at 70wpm, and I cannot understand n't work out well for him and he how any XXX living man can do the same, because I know that the signals I am copying can't be read [copied ?] by anyone else, that is, without error.

McElroy wrote: "I want to tell an overall general speed increase advice really won the title. I will speed. never forget the debt I owe you.' [Notice that this totally refutes the rubbish he wrote as to how much Candler's method had helped him.]

Borsody, in a letter marked in ink "received April 1975" to Eitel that he clocked McElroy at an informal run ["I invited him to sit down and take a little workout receiving some high-speed code. My sending operator, Jack In 1974 the "Curtis KB-42ØØ sody says that he and Taylor veri- typing' fied McElroy's [later] contest speed as 76 wpm, containing technical material with which Ted could not have been familiar.

Ted also said at another time that he could read the code much faster as many others he knew also could -- it was typing which limited him.

#2 Lavon McDonald

Was another commercial operator, but a radio operator equal with McElroy. He definitely tied with Ted McElroy in the 1939 contest. No further information on him, except that he was also a ham.

Keyers

II. Keyers made it easier to send faster, and there must have been

you that I very deeply appreciate with their arrival in the 196Ø's the help you give me in winning But it was the keyboard that really the title.. Your equipment and started the great step upward in

Eimac Co. in 1934... He was a deep thinker. Most of the following materials are in his own words.

The potential of Morse code for communication between individucommunication, using the benefits als and not as a means of hanof modern equipment, expands dling messages, we have a whole our past ability in a manner never new set of circumstances and thought possible. Some amateurs benefits, it is no more desirable to have been and are talking together with Morse code at speeds down a phone conversation. of 8Ø - 1ØØ wpm or more. These new high-speed operators accept new equipment as a means of improving their operating ability (a tool) and not as a threat to their status. It has and is being done. It is interesting to note that the 5-Star hams attained their speeds using keyboards having no memory such as we have today.

Because with our older tools could only send so fast, is this really also the upper limit for our receiving ability? Let us not resist either improved operating methods or equipment that will allow better use of the code for some vague "romantic" connections with the past -- history.

Taken from a file of some of his Have we forgotten the history of letters and replies from friends keys?. Stop and think of the gains in ease and speed when we went from a straight key to a sideswiper, to a bug, then to a keyer! Is a keyboard something evil?

Official government messages, diplomatic and military required absolute accuracy, but when we see the Morse code as a means of "put it down" than it is to put

This use of the code can become a challenge both to master the code and the associated modern equipment available at speeds above and below 8Ø wpm. E. g., in a round-table one can transmit a thought while waiting for the VOX to respond to SSB.

Yes, there may be some whose physical or mental limitations prevent these speeds, but the biggest deterrent is the lack of a real interest.

Once you determine to master the Morse code, I believe it will be found that practice can be as much fun as operating. The most important and final ingredient is the determination to use the keyequipment. GOOD code becomes easy at high speeds.

overcome.

5-STAR club originally required 7Ø wpm, but soon raised it to 8Ø wpm. There were four other members originally, but by 1974 had increased to a total of 1Ø. There must have been others also.

(See QST November 1974 page 155 for a good photo of Bill and his wife Laneil in an ad promoting the Ten-Tec Triton as working well with high-speed code keying input. The letter-head gives the Butro Ranch and Labowas dated August 24, 1974.).

#5 Tom Alderman, W4BOF.

First person story:--As a boy of 8 or 9 I was wondering what my Dad found so entertaining about sitting at a desk copying all those dits and dahs; but I could tell that it was something he greatly enjoyed as a CW traffic net operator..

fun .

Before I had finished my year as a Novice ham, I too, was into CW traffic nets and enjoying it tremendously. So for the past 49 years (since 1951) I've been en-

board, and any other useful joying CW and still think of it as "fun"

I'm still enjoy high speeds at near Good spacing tends to be a prob- 8Ø wpm as W3NJZ, K3TF, lem, but one that practice can KB9XE, and I 'harass' each other on Wednesday night for about an hour on 3.533MHz. My real high-speed pal, Ira-NU2C, used to 'challenged' me to actually determine how fast I actually could read code. We found the maximum speed that I could understand and correctly respond to his questions, was 144 wpm. (I am not a "freak" -- hi..hi).

> I suspect the starting key to being able to copy high speed code is one's initial learning attitude. It may be strongest factor.

ratory at Dayton, NV 894Ø3, and I believe that learning code has forever been talked about just like we talked about that 'awful' mathematics stuff in high school, therefore most potential hams start off with a 'bad' impression of code.

I'm pretty much convinced that there is a 'speed hump' that most hams (myself included) seem to have a problem exceeding. I think that speed hump range is between Therefore, I didn't start hamming 45 and 6Ø wpm. Almost everyone with the slightest negative attitude I have helped get into the 6Ø+ about code and so I never gener- wpm area, have had an extremely ated the attitude that "I'll never be difficult time debunking that able to do that". In fact, copying mythical 'negative attitude' and CW is one of the great enjoyments actually copying faster than that that I get out of this hobby. It is hump. I can imagine what most of them thought when I would tell them to try not to think of copying 6Ø wpm as something they can't do, think of it as just learning a different way of talking. Because I'm convinced that QRQ CW is one just conversing in a second language.

concentrate on the code, I con-There is no difference in doing that, as having a native American converse fluently in French.

Code Readers

It certainly bugs me that most hams think that if your using a keyboard and/or your running CW over 3Ø wpm, that you MUST be using a code reader! (I think that's another part of the universal negative attitude about code.) Sometime around 1968-69 I began trying to copy the QSO of the guy in New York and the guy in Florida, who almost nightly held a 1ØØ wpm one-hour long chat. My wife (I still don't know how she found out about them) bought me an Info-Tech Morse code reader for my birthday, which of course I, at that time, sneered at. But I found that when I was trying to copy the 'hump' speeds around 55 wpm, if I missed a letter or a word, my concentrating on deciding what which advertised in QST. [Quite a

How does one read CW in excess word I had just missed therefore of, say 8Ø wpm? I can honestly losing total concentration; by tell you that I have no clue! glancing up at that code reader, Around 5Ø-6Ø wpm one no my brain would be quickly satislonger copies dots and dashes, fied, and I would continue with they literally begin copying the copying! At the time I didn't words. As the speed increases, I realize this was actually happendon't think your copying words ing, however after about a year of any more, you get into the flow of this, it suddenly dawned on me the conversation and literally be- that I was not looking at the gin copying phrases or complete reader any longer and I was sentences. Interestingly enough, I copying in excess of 6Ø wpm. In find that when copying over 800 a sense, we are pretty lucky with wpm, I don't even realize I'm code readers, they copy extremely copying code, unless a major well in the speed ranges we need word is either misspelled or really them to help us get over the hacked on the keyboard. I don't 'speed hump' but with the QRN of 4Ø/8Ø metres, once you try to get centrate in what is being said. them to consistently decode CW over about 7Ø wpm, they just cant do it because of the normal band noise!

> He says "There is a lot more to be said on this subject. zzz'

#6 Bill Pletting KB9XE

He was about age 35 and was enjoying personal radio communication with CB. It was real fun. His CB buddies were having weekly get-togethers just to socialize. Then he discovered that one of them was also a ham, whom he visited in his home. Bill was astonished to hear Morse code and, like many others, apparently had never heard communications in Morse code before. It fascinated, intrigued him.

Then and here he became so enthusiastic to learn it that he bought a set of learning cassette tapes from Amateur Electronics Supply,. A reputable and wellbrain would freeze up and try known company in Milwaukee, few others also had such courses, Now Bill got a transceiver and including the ARRL.]

those dit and dah characters, that he quickly learned the sounds of tapped out the code with his finthe alphabet, numbers and punc- ger.. He knew he needed to build tuation, and within a couple of up his code speed to be able to weeks he had begun to practice read most signals. He did so well wherever he was and would not disturb others. He would tap out Novice license, he took and sucall kinds of stuff with his finger as if using a key .-- or saying them in "dits and dahs" (At home it was With total access now to the ham so bad that his wife was getting irritated!)

He was determined to do it. Apparently he did not question whether it would be either "hard" or "easy" .-- he just did it. So it was "easy", because he never thought of it being "hard". He eagerly wanted to do it and Higher speeds were a constant learning was enjoyable -- fun. . And because he started learning it as it is used -- hearing it and sending it as sound patterns -- he minute of it.

It was "easy" because it wasn't During this period a number of thing to be enjoyed and done -to listen to amateur signals.

Meanwhile he also read and understood or memorized the answers to the necessary technical questions and regulations so that within a month he took and easily passed the 5 wpm code text and the written test, and soon received his first license - as a Novice.

went on the air using code ac-Bill became so "obsessed" with tively in all QSO's. But also often away from the radio he just that within a year of getting his cessfully passed the Extra Class license (2Ø wpm) exam..

> bands he tried RITTY and some other digital transmission methods, but absolutely nothing could hold his fancy like Morse code did. He was also discovering that the more you practice doing a thing the right way, the better you get at it.

challenge. He still kept hearing stations that were too fast to understand, and he wanted to understand everything he heard. -did not have to do any relearning. these were like a spur jabbed into He was learning it in the perfect his side. Lots of experience.

Since 1946, during part of his various jobs, he managed to teach amateur radio classes. He helped He got interested in ham radio in a total of some 3,500 students to High School when a friend's obtain their amateur licenses. He transmitter penetrated the school loves teaching Ham radio and

He observed that over this long period the average age of applicants gradually increased by 15 years and it was taking longer and longer to teach them the code. To attract high speed code operators and learn the secrets of how they gained that skill, he started giving When he was having an early code contests at various hamfests. health problem, he saw learning This wasn't just for the fun of it the code as a goal to help recover he wanted to learn more and bet-

He applied what he was learning to his own practice and he began He decided to become a part of to approach the 1ØØ wpm rate the magic world of radio, so when for copying. But he was disaphe finished high school (about pointed that the same things did 194Ø) he entered a radio and not help the students to improve telegraph school to learn the code greatly, as he had anticipated. He really well, because it seemed to researched books on the psycholbe a prerequisite to progress.. ogy of learning, etc., and found

success in teaching how to copy code:--

- 1. First and foremost, the student must be strongly selfmotivated. But it was hard to convince the students of this.
- **Diet** The over consumption of sugar, pre-processed food and meat products seemed always to impede the code-learning process. [Note that Candler said much the same thing yeas before.].
- Exercise (such as push-ups, running, etc.) before and after practice periods [Candler also agreed here, but in his day cramped working quarters, poor sunlight and air circulation were common problems.]
- Correct methods of code practice. Successful code learning results in the individual copying totally by subconscious mind activity, but that does not occur until the mind has been properly trained. [Lewis was aiming at copying ability, not just understanding.]

Another factor involved the rise and decay times of the code signal envelopes (the dits and dahs), the frequency (pitch) of the tone and its timber, etc., adjacent vowel and consonant combinations, etc., to optimize the impression to our ears.

to copy at very high speeds he replied "at 75 to 85 wpm there is and special procedure signals

involved if one expects to have absolute concentration, almost to a state of hypnosis." When asked if he could start copying immediately at 75 wpm, he said "NO! I would have to prepare myself psychologically first, and that takes from a few minutes to as much as 45."

> He then was asked if he thought there is an upper limit to receiving speed, he said "It is definitely above 12Ø wpm, because his friend Jerry Ferrell had been clocked at 90% complete reading at 125 wpm."

> He was certified by the ARRL in 1988 at 76 wpm copying. Now with advancing age (7Ø) he feels he is slowing down somewhat.

#8 George Hart, W1NJM,

A long-time ARRL headquarters ham. First Peson story:-

In 1924 in a small town in Pennsylvania Ed Hart became a ham with an operator's license and call 3NF. His little brother George was curious. What was this Ed was doing and having so much fun with? Was it some sort of new language he was using? What did George have to say about it?

"I admired my big brother Ed. He was my ideal. He was 15 and I was 1\,\text{Ø}. I began to learn the code like a baby learns to talk -- by listening to my brother operate and picked up the "code" by 'osmosis' - recognizing and imitating the more frequent sounds I heard.. I wasn't aware of any such thing as "dots" and "dashes", but only of symbols with mean-When asked in 1991 what it is like ing. I quickly learned the sounds of his frequent CQ's, his call 3NF

between calls), R (signal strength), and absorbed other sounds, as sounds with meaning. I just sort of drifted into it by listening. must have been born with a key my mouth.

"I didn't start out with any determination to learn the code, or to ful 'glass arm'. When keyboards get a ticket, or on the air. .But one came out he found he could send day -- it was 14 Sept. 1926 -- I with his two-finger method up a made my first QSO with W9CRJ to about 55 wpm. in Lexington, KY, using my brother's station. When I was 12 I discovered I had mastered it and was able to carry on a conversation. I could communicate like he did, I could do 34 wpm sending with a straight key. Finally my brother Ed bullied me into getting a temporary license in 1931. The code was not a problem, but I barely passed the written theory test with a grade of 7Ø. I received the call W3AMR, which has a great CW swing and I learned to it right in the beginning and conlove it. I wasn't capable of building my own station yet.

"So my advice is to acquire proficiency in code sit and listen, and keep listening and want to understand it. Anybody who's learned It's that to talk can learn CW. easy. Just live with it and it will another way of talking."

Learning conversational CW is more like learning to talk than it is to learning another language. It is far easier - you don't need to learn how to pronounce strange new kinds of sounds, learn a new vocabulary or a new grammar. It is just recognizing the simple mono-tone sounds and imitating

such as ARK (now DE), U (used them. Learning it is "all a matter of incentive.'

> "I was given a Vibroplex key in 1929 and in my late teens and early 2Ø's I could send almost like a machine at 45 wpm. But first with straight key and later with a bug he developed the pain-

> "I never learned touch-typing, so this is a handicap with the keyboard. I use two-fingers and when copying text to send the maximum I can do is was 55, because I must keep shifting my eyes back and forth from text to keyboard quite rapidly. Thin not only slows me down, but promotes errors increasingly as I grow older.

"In my opinion high-speed CW is a natural progression, if you learn tinue to practice it ".For receiving George has for many years been able to read code up to almost 8Ø wpm, but now he can only send about 4Ø, and so his QSO's today are rarely over that speed.

Most of the time since 1957 he has actively promoted high-speed come to you. Morse code is just reception by putting weekly practice periods and occasional qualifying test sessions on the air, and awarding certificates of proficiency. He did this first from a small club he formed, advertising in the QST. Later with help from friends in a the Society of Wireless Pioneers. His transmission were made using a tape puller at speeds ranging from 20 wpm to 70 wpm. Only recently has he ceased doing this.

wpm. He feels he could maybe higher speeds he heard. make 4Ø in copying it down.

dizement is a basic motivation of playing. He does not need any the Amateur radio pursuits, especially DX-ing and contesting. We do what we do because we enjoy it", and some do enjoy it purely for itself.

#9 John F. Rhilinger, KC1MI,

to copy at 7Ø. In 1992 I asked nice letters. Here is the essence of what he says was his experience...

His father W1QQS was a close friend of Ted McElroy, the long time speed-record holder, who frequently visited them, and whom he knew as Uncle Ted. By age 6 he became interested in Morse code and from them at that time he learned the code up to a #11 Jerry A. Ferrell WB7VKI rate of 1Ø - 15 wpm, but did not get a license.

sleep-learning. also actively hamming six hours a characters -- far below their rec-

Now he rarely sends over 3Ø - 35 day and probably aiming at the

He has not sensed any loss of rest He feels that "personal aggran- during sleep with the recorder prepping-up to start reading at high speeds. He just starts. Typical misspellings and other such errors cause him no problems in reading. He does not lose out..

#1Ø Katashi Noshe, KH6IJ.,

Was able to read at 8Ø wpm, and was a long-time ham, a DX man and code teacher. What his top him some 22 questions, each of speed was is apparently not rewhich he answered, plus several corded, but he used up into the 6Ø wpm range in DX, and his students advanced rapidly from zero to 3Ø - 35 wpm with no problems. In 1959 Katashi Nose KH6IJ wrote "Any DXer worth his salt is good for at least 6Ø wpm. He gears his speed to what comes back." He was a wellknown DXer.

(CFO # 76Ø) is another very high-speed operator. (over 100) In his later years when he had be- wpm with whom I had extensive come a ham and reached a speed correspondence in 1992. He was of 3Ø wpm, he began to practice born in 1927. In 1945 at age 18 (Sleep-learning he joined the US Coast Guard and was a method successfully tried aptitude tests showed he should by some in the early 1920's.) make a good radio operator. He Generally he practiced it up to was assigned to the six-month rafour hours each night. He used a dio course at Atlantic City, where tape recorder to send continuous the goal was 200 wpm of ciphered code materials previously heard 5-letter groups. Only a very little and recorded at various speeds, standard English was practiced and speeded up ultimately to the toward the end., but he was not 6Ø wpm range or higher by the too good at that.) Otherwise he recorder play-back (running 1- was at the top of the class. The 3/4 inches a second.).. This seems course plan at the CG school was to have been the main way he to start out at some 5 wpm (apreached the higher speeds. He was parently using very slow code

ognition as patterns, which occurs he bought a reel to reel tape rein the range of 1Ø-13 wpm), and corder and a keyboard and made progressed faster by one week at a some 5Ø large reels of 1/4 inch time increments until reaching tape at speeds ranges of $5\emptyset$ - 75, 2Ø-wpm.

After school he started out on US CG ships, but left for part of 1948-9 and went into RR telegraphy. He spent one month at their telegraph school for the American Morse code and then went on temporary assignments. Later in I sent him a list of questions 1949 he returned to the USCG and stayed until his retirement in 1966. During various assignment in the CG he copied normal English messages at 2Ø-25 wpm, and press broadcasts for the ship's newspaper at 35-4Ø wpm. He was so good that sometimes the shore station operators would punch tapes to send to him at $5\emptyset-6\emptyset$ wpm to try to trip him up - but he did not miss, and they wondered what was going on. Then for a period of 12 years, 1996 to 1978, he worked at different occupa- 2a. tions with no radio or telegraphy activity. In early 1978 he got a ham license. And in May that year he visited the Vancouver Ham Fair. On entering the building heard code signals and located their source, as a code speed demonstration for a crowd of spectators being given by Harry Lewis who had a keyboard, a TV monitor and a meter showing sending speed. Jerry asked for a try, starting at 3Ø wpm and increasing by 5 wpm increments, copied up perfectly through 5Ø wpm. At this time he became friends with Harry Lewis who from then on lent him equipment 2b. For him, he finds it hard to and helps, and encouraged him to increase his speed capability. So

6Ø - 8Ø and 7Ø to 9Ø wpm for practice. Later he made more tapes with 5 wpm speed increments between 5Ø & 8Ø, etc. He has a 75 & 1ØØ wpm. "warmup" tape that makes the others seem rather slow.

which he answered in considerable detail:--.

- He rightly suspects that the main reason for the increase in number of high speed operators is the widespread use of keyboards for sending, but as for keyboards which also receive, I have heard of none. (Some computer programs can receive, however, but I do not know how fast.).
- He felt that it would be so stressful for an operator to copy at 6Ø wpm for 1Ø -12 hours daily as to be virtually impossible. He feels no strain while reading, but high speed copying stressful for him. He is quite correct that reading code and copying code are two different kinds of operations -- copying being by far the more difficult. This because one must get the code from you ears, process it through the brain, then on down to your fingers to the typewriter.
- sustain for very long. It is with this he must practice

for an upcoming contest. For the upcoming contest in five months he would spend at least an hour each day. He must also get psyched-up before a contest.

- 2c. He says he is sure that the secret of learning to copy at higher speeds is to start out listening to and trying to copy 1Ø or so higher than one is comfortable with and then dropping back. Like driving a car at 9Ø mph and then slowing down to 8Ø seems slow.
- 3. He says that to him International Morse code at 75 wpm or more sounds like "chicken fat in a hot griddle." To start reading it he has to make up his mind to break into it and begin concentrating on words and phrases.
- Then so long as he consciously maintains his concentration, he can continue to read it. What does he concentrate on, and how does he do it? He visualizes it as something like this -: "Listening to a news broadcast on the radio while reading the daily paper, one or the other will have priority of attention: While I focus on one, I am conscious of the presence of the other, but not fully aware of its contents- in fact it is may be more or less gibberish to me." [Paraphrased This is an inexact parallel, but it is this snap-

- ping of attention that makes the difference between reading and hearing it as noise. Hard or unusual words, etc., are sometimes difficult, but generally do not cause drop-outs by destroying overall concentration. He may be conscious of missing something (due to misspelling or sending error, etc.) and be momentarily puzzled, but not for long, as he continues on. Attention is on understanding - that keeps him going. Long words do not cause any problems.
- 5. He does not know whether there is a limitation on the speed of understanding, but thinks there must be.
- 6. He has always been able to listen to the code or send it while doing other things -- typing at moderate speeds, conversing with others, retuning, etc. While he was a shipboard operator and returning with others from shore leave after being still somewhat inebriated they would sometimes try to trip him up by sending him words spelled backwards, etc. But he did not trip up.
- 7. Although he can read and copy American Morse up to around 3Ø-4Ø wpm it does not sound right to him with a CW base. He does enjoy reading it occasionally from taped sounders, however. He never practiced at higher speeds.

#12 Frederck M. Ryan W3NIZ (b. 1932 -Ø1-2Ø)

In about 1942 when he was 1\,\text{\text{\$0}}\, Fred's Father as a Christmas gift, gave him a toy telegraph set which could be used to send between two stations, using a buzzer, a clicker (sounder simulator) or a lamp. There is no doubt as to why he was given that. His Father go any faster anyway. was a telegrapher on the Pittsburgh and Lake Erie RR, his Grandfather was a telegrapher on the Pennsylvania RR, and an uncle on the Baltimore and Ohio RR. He taught himself the letters and numbers by memorizing them at a very low speed..

After WW-II when ham radio was again allowed, he decided to improve his code ability and take the exam. He practiced on his telegraph set and also mentally putting advertisements (posted in the trolley car during rides into town or in newspapers) in to code. His Father was not much help because he knew only American Morse.

He took the test in 1946 and failed the 13 wpm code exam. At that time one had to wait six months before trying again. So, during that interim he practiced more, as he had previously, and remembers that his sending speed was good up to 18 - 2Ø wpm, but he barely made it at 13 wpm, and so successfully passed it early the next year.

terms of "dots" and "dashes", copying and thinking approach recent ham practice speaking in so I bought a keyboard and

terms of sound as "dits" "dahs". Whether he learned it by sound or visually, he says he was sort of "stuck" at the test speed of 13 wpm for a while. He had little time for speed building because he was busy with high school studies, and since that was the limit of most of his contacts he felt no interest or incentive to

In the early 195Ø's when he was in the Army he was using a straight key up into the 15 - 17 wpm range.

Sometime in the 196Ø's his first real improvement began when he started listening to the ARRL code practice transmissions in preparation for taking the Extra class exam. He knew from experience that one tends to do worse under test conditions, so he waited until he could copy at 3Ø wpm before being tested at 2Ø. Of course he passed.

On into the 197Ø's his comprehension and sending speeds increased slowly to about 4Ø wpm, when he used a keyer for sending and was no longer copying it all down. In the mid 197Ø's, when keyboards became available, he heard some fellows sending over 8Ø wpm, but could understand very little of what they were saying. He thought that would sure be fun to do. But he thought "They are really in a different league than I am and what they Since he expresses himself in are doing is above my ability. I had little time to try it because of he probably followed his father's the pressures of my job.". "When I retired in 1992 I finally and practice, rather than the more had leisure time to spend on CW,

started sending at 45 wpm. Then He began his experimenting and QSO"s at over 6Ø wpm, I decided wpm. Successful changes were: I could would see if I could improve to that level.

"It took a lot of desire and practice, but over the past three years (from 1997 to the end of $2\emptyset\emptyset\emptyset$) I have gone from 45 wpm to over 7Ø wpm. I intend to keep it up and improve more. It has been a lot of fun, and I have met some 3. great people also who acted as mentors to me."

In his own experience he says he finds the way his brain functions is:- "below about 55 wpm I start 4. constructing the words from letters, and comprehension is thereby cumbersome. Especially below about 25 wpm I find that my attention span in remembering the slowly incoming letters and constructing words from them is tedious. Above 55 wpm my brain starts paying little attention to the letters, and the words just "pop" into my head. Even at 9Ø wpm I am still getting words and putting them together to form thoughts. 9Ø wpm seems to be about my limit to do that, and I believe that to comprehend over 9Ø wpm I will have to change the way in which my brain operates. Further practice and time has raised his comprehension speed to over 1ØØ wpm.

Raising His Typing Speed

Fred tells how he improved his sending and reduced the number of errors at speeds over 7Ø wpm on the keyboard. He experi- 6. mented and found that it took about ten days of practice to exceed 100 wpm. .

he heard some guys holding practice at his then present 700

- He turned off the side-tone completely, and.
- stopped looking at the screen, except maybe a glance when his fingers tell him he has made a mistake and,
- He did not look at the keyboard either. These three changes eliminated the distractions, so he could concentrate on his fingers;
- While he does not look at the keyboard, he "visualizes" it, so he could mentally concentrate and direct where his fingers are going to go next. He just "wills" his fingers to go there and they do. It is rather hard to describe.
- He compared it to this: "When I was seriously into playing the piano, although I was aware of the presence of the piano keyboard, I never looked at where the fingers were going to go. Even if I was jumping several octaves quickly, I could hit the proper note(s) exactly without ever turning my head. Looking to the keyboard to see where the fingers were supposed to land would have made good piano playing impossible.
- Within a couple of weeks of experimenting and practicing, he found he could send as easily at 1ØØ wpm

as he had before at 7Ø.. But what most surprised him was that now he could chat just as easily at 1ØØ wpm as he could before at 7Ø. He said "I can get the thoughts organized in time to keep the fingers busy at these higher speeds. When I had mastered this technique, I found to my surprise that getting the thought-flow going at 1ØØ wpm became very easy. I was wrong".

One further thing -- he needed to improve the cadence of his sending .-sending each letter at exactly the same rate. said: "Errors that I make, such as sending "adn" for "and", are due to hitting the "d" finger out of cadence, too quickly to allow the "n" finger to type. Now I concentrate on keeping the cadence constant, something that I have never done over the past 5Ø years. I had thought that would be the really hard thing to master. But it wasn't.

How observant and thoughtful he was. Are these suggestions I need "Gene taught me how to increase to follow? "Gene taught me how to increase when I got to one solid

He has noted that in his 53 years of hamming he has not operated a great deal-- typically less than an hour or two a week. Even now he is fortunate to find one week in a month when he can communicate with a truly high speed operator. High-speed operators in the U.S. are rare today.

#13 Ted J. Newport

(b. 1919-Ø9-11 (age 81) First person account. "I learned code when I was in flying school during WW-2. We had to send and receive 12 wpm before we could start our flying training. After the war I bought my son a short wave receiver, heard CW on it, and relearned the letters I had forgotten. I taught myself code with tapes and with friends helping me on the air, I owe what speed I have through the help of two friends both deceased, who worked with me on the air for years, helping get my speed up. The were Jimmy Moss W5GRJ and Gene W4JKT who kept pushing me.

"First you must have the desire to learn CW, and to like/love CW, and have the desire to increase your speed, instead of staying at a plateau.

"Next, practice practice, practice. When you reach a solid copy speed, then you must have the desire to want to go up to the next level of copy speed. Tapes are fine, but the best practice is to get on the air with friend who will push you to the next level, and who will send to you on a regular basis.

"Gene taught me how to increase speed. When I got to one solid copy speed, he would increase ins sending speed. When I could not copy solid at the increased speed, he would then send to me at a still higher speed. I was not able to get too much of it, but when he dropped back to the one I could not copy solid, it would then sound slow and I could copy

solid. In other words, he would He spent most of his time in the not slow down when I wasn't getting solid copy, but would go to a when it was bombed. still higher speed and let me listen to it, even if I could only get a word or two, and then, when he (b. 1946- Ø3-Ø5). He learned the dropped down to the lower speed, it would seem slower then and I W4BI, (see above) who started could copy it. "I cannot copy teaching him the code when he and send as well as Tom Alderman and the others do I don't get on much any more and my reading (not copying) speed is in the range of 6Ø to 7Ø wpm.

#14 Rodney L. Whitten W4BI

(b. 1912-Ø4-22) is one of our oldest available examples of very high-speed operators. His interest began in 1924 when he was 12. .

Spark was beginning to lose its rough, noisy thrill and sense of power (like a motorcycle), and was going out of use, displaced by the tiny vacuum tube with its peeping CW signals and the rapid increase of DX occurred as "short waves" became shorter and shorter -- into the "useless" range.

He was interested and wanted to learn. .

He joined the US Navy in and was He was able to copy 4Ø wpm up selected to be a CW operator. He was trained as one of that special crypto "over the roof gang", an elite

bunch of guys trained to learn various codes (he learned to copy 8 different codes) before and during WW-II. In all they included some 178 men who were so trained. Their work included QRQ copying..

south pacific and was at Pearl

#15 Melvin L. Whitten KØPLX

Morse code from his Father, was about 9 or 1Ø years old.

Since his Father-teacher was a QRQ expert, Mel was never troubled by first "memorizing" the code visually as printed dots and dashes, but rather heard it as it is, as patterns of sound.. Furthermore, he must have had no concerns as to whether it was "hard" or "easy" to learn.. It was just to be learned like anything else. If there were any difficulties along the way, his Father encouraged him to keep on, with something like: "Look how much you have learned and can do already."

Then, because the FCC office was 15Ø miles away at the time, he used his Father's call sign for a couple of years until finally he managed to get to the FCC office for the test and to get his own license and call in 1958.

until somewhat more than 2Ø years ago when both he and his Father got electronic keyboards. His sending speed began to go up and along with it his copying speed rose to 45 then 5Ø and finally reached 55 where it started being work -- above that he must sweat up to his absolute limit of 6Ø wpm. His comfortable range is 45 - 5Ø...

He says he owes his "QRQ" to 35 years of QSO's with his Father who has long been able to copy over 6Ø wpm...

He feels that if he would work at it, he is sure he could increase it even more. "It just takes a lot of practice."

#16 Ira I. Silverman,

No data other than that he is a very fast operator, can type into the $14\emptyset$ wpm and receive at least to $1\emptyset\emptyset$

#17 Oscar (Ozzie) Levin W5RK.

(b. 1918-12-4) This is one of the most interesting cases, for it illustrates "normal" learning.

He "got interested in Ham radio back in the mid-thirties after visiting a Boy Scout that had a ham station." - He was more than just "interested."

- 1. He wanted to learn the code and had no preconceived ideas about it. We may say he loved it already.
- He started from the concept of the code presented as sound --: "spoken" dits and dahs -- not printed dots and dashes. He had no visual road blocks. What did he do? -- He "learned the code on his own" because he "had no mentor or anybody to send code to him." He learned it by looking at a newspaper and saying the dits and dahs to himself for all the letters and numerals in the story he was reading He took the examination in

- 1937 and passed both the 1Ø words a minute code test and the theory test.
- 3. He had no initial mental blocks -- that it might be "hard" - but rather just "that's the way it is", something, like everything else that he wanted to learn. He enjoy learning it. It was fun. Without the excess misdirected baggage so many unwittingly carry, he reached a 5Ø wpm copying ability in three years. His evidence joins the rest of that relatively small group who did it right from the beginning and had nothing to have to relearn.. That is why it seemed "natural" to him. He "entered the Coast Guard in 1941, just before we got into WW-2, and was assigned as an apprentice Seaman operating the highspeed circuits along with veteran operators. {After another assignment} he left the service in 1946.
- 4. For ten years he was inactive, though he continued his license. In the late '6Ø's he ran into the Chicken Fat Operator's Club [CFO's] where one of the operators observed he had been copying the high-speed and asked him if he wanted to join them. He did, but soon found he could not keep up his sending speed with just a paddle, so he built an electronic keyboard.

The use of a keyboard, which is only a tool, is the almost

universal newer hardware key which gives that boost to pass the frequent "plateau", the speed "barrier" around 5Ø - 6Ø wpm.

Some kind of internal change in mental approach seems generally needed (Is it a change that is hidden from our conscious understanding?) .He could now practice well-sent code at home or during QSO's with others using keyboards. (Bug or keyer sending is a special skill that not many achieve at those speeds).

This change resulted in a noticeable increase of his receiving speed and he was soon sending 7Ø wpm. "It was a wonderful exhams using these high speeds.

#18 Florence C. Majeras W7QYA

b. 21-1Ø-1915. Bill Eitel said, "She is a very talented and pracments are many and unknown to transceiver, power supply, tuner most people, because she is a and filter which at our rented modest and sincere person. She is house, put me in regular contact a pilot, musician, school teacher with other CFO members and nets and a top CW operator. She does whenever possible. He also connot have to take a back seat to any nected us home to our teenage one when operating CW. She can children through the ZL packet send it, read it in her head, or system. When I went back to ZL, copy it down on a manner which we kept schedules on 400 when people do not realize because she conditions were right. Later went I is no show-off. She is the kind of returned to Ann Arbor several to recognize."

I have no information as to how she learned or when she started into ham radio.

#19 Gary Bold ZL1AN

is the only known New Zealander who belonged to the CFO club. He says: " $4\emptyset$ - 45 wpm is as fast as we ever go. Keyboards are not in general use. He was quite astonished to learn that some hams in America were conversing in Morse code at 1ØØ wpm. Gary had himself written computer programs to read code at fair speeds, and using them, managed to reach his present limit at 55

#2Ø Jesse W. Caravello, Jr. W8MCP

b. 1936-Ø6-Ø7 The following comments are from Gary Bold perience." Today he finds few ZL1AN. In 1985 I visited Ann Arbor on Sabbatical leave and encountered him on the packet system. He invited me to visit his home.. He told me he was also a CFO Club member. I thought it was defunct. Learning that I was tical woman. Her accomplish- rig-less, Jess lent me a SWAN person I formed the 5-Star Club times, each time I enjoyed his and his wife Brenda's hospitality. They became very dear friends to me.

> I know virtually nothing of his early Morse experiences. I am sure that he would have told me everything. A couple of years ago

Jess passed away, I think due to a b: 1944-Ø8-Ø1, massive heart attack.

Jess was, indeed, a first class CW man. I know he had spent time as a sea-going operator. I don't Charles H. Brown, JR, W4AFQ, know how fast he could receive, and I never saw him use a keyboard, but he could read any- Wells E. Burton, N4EE b: 1919thing. He could copy noisy, weak signals covered in static and QRN from which I was gleaning mere letters and occasional words. Strange fists were no problem to him. Nor do I have any information on the following names who are supposed to be very highspeed operators:-

David H Freese Jr. W1HKJ

Wrote software for 99 wpm and on Bill Eiel's request revised it to run at 16Ø wpm. No further information on him.

Others in the high-speed class on whom I have no other information:--.

Fred C. Clarke W9AMC. Christ C. Kovacheff K9AMC, David H Freese Jr, W1HKJ,

Charles F. Vaughn, III, AAØHW,

b: 1958-Ø1-18,

J Philemon Anderson W9TP

b: 1929-Ø5-31,

Raymond H. Larson, WØGHX,

b. 1936-Ø8-Ø1,

Charles F. Vaughn, III, AAØHW,

b: 1958-Ø1-18,

J Philemon Anderson, W9TP,

b: 1929-Ø5-31,

William Sepulveda, K5LN K5LN,

Carlos Dale Hamm, W5LN,

Melvin J. Ladisky W6FDR,

b: 1928-Ø5-28,

Ø7-14

Other older operators for whom we have no data on their leaning methods: Frank J. Elliott, Cpl. James Ralph Graham, at 6Ø wpm or more:-- A.J Burkart (1913), E. Proctor, W5FDR Earnest L. Sitkes (W4AFQ), W5GET, W9RUM, William L.Gardiner, Wells E.. Durham (N4EE), Cpl G.Schaal, others in Eujrope, who used these speeds daily

There were nearly one thousand listed members of the Chicken Fat Operators club, which required at least 45 wpm for entry, before it faded out as a club a few years ago.

I suspect that the number of highly skilled commercial operators and hams around the world who can or could receive at over 45 wpm would add up to many thousands, with a large number of them capable of well above 6Ø wpm.
