## A DualBand Power Amplifier

Auto BandSwitching LDMOS Power Amplifier for the Amateur 2 M/70 cm Bands

Rear/Top View

## Circuit Description and other Musings:

It all started with a need to make my mobile FM setup more organized and less haywire. Ask anyone who seen my car. The end result is a neater solution with an auto band-switched unit that gives the amateur radio operator an indication of which band is being transmitted on. It allows for low-insertion loss on receive, and silent reliable T/R switching using PIN diodes. Based on some very good experiences I have had in the past with power MOSFETS [1] , I chose to stay with that device type. In this case, these are LDMOS devices that Woody, AK2F located for me [2]. These Mitsubishi units were not difficult to use, and the same can be said for several NXP and PolyFet devices I have used in past projects as well. The gain and power was as expected, and the data sheet information proved to be useful.

This document is meant to be self-explanatory, not a point by point construction article. It is intended for amateur radio use, not commercial or any other use. The amateur builder with some RF experience can see from the photos, schematics, parts lists and test data pretty much what to expect. If you are capable of UHF construction you already know all about short lead length, good grounds,etc. The low-inductance advantages of using several small-value ceramic chip capacitors in parallel verses one big chip cap,etc. Of course, any component substitution of any kind carries some risk, so be aware of this. It is suggested the reader reviews Tables 5,6 and 7 throughly.

Since this project uses LDMOS FETS, which can be static sensitive, it makes sense to use a ground wire to the Q1's gate. Attach (tack solder) a thin bare wire from Q1's mounting flange to the gate lead after removing it from the manufacturer's ESD packaging. Mount and install Q1 (with the wire) after all the other power amplifier components are mounted on the Power Amplifier PCB. With Q1 mounted in its PCB cutout, solder the gate and drain leads of Q1 onto the PCB. Then snip the bare wire.

This document being written January 2009 hopefully concludes this project which started in October 2004. The first item was the 70 cm power amplifier with T/R switch and detector followed by Band-Detect circuit, diplexer and finally the 2M power amplifier with its T/R switch and detector. If the reader wonders why one would use "lumped components" at 70 cm and "microstrip" at 2 M for the power amplifier circuits, I will say "Because You Can!" For whatever reason, that's it's just the way the project evolved. Note that the 2M T/R switch is "lumped" while the 70 cm T/R switch is "distributed" (coax). This Rev A addressed a problem of small capacitors at C6 and C8, which could fail due to high RF current in the drain circuit of the 2 Meter PA.

APPENDIX A. SUGGESTED PROCEDURE
When taking on a project of this magnitude, it helps to break it down into manageable portions. The following sequence of construction/test proved helpful. (Still, this is not intended to be a construction article!)

TABLE 5: SUGGESTED PROCEDURE

1 | Power Amps Assembly (omit and bypass T/R Switch/detector |
| :--- | :--- |
| circuit). |

2 Test/Tune each Power Amp. Set each gate bias potentiometer for 0 V initially. Adjust it gradually during tuning process. Apply +12 Volts and +12 V TX ( 2 M or 70 cm ) manually to each. RF input power of approx 2 watts was used. With +12 V and +12 V TX ( 2 M or 70 cm ) manually applied and NO RF power input, the quiescent drain current should be similar to values in "Measured Data" table. Once you adjust the Quiescent Drain Current for the

3 Build T/R Switch and Detector circuits on each power amplifier board.
4 Test Power Amps with T/R switch and detector circuits. Apply +12 V TX to the T/R switches to enable TX.
Test the detector circuits for DC output with RF applied. Detectors should work over the range of $\sim 200 \mathrm{~mW}$ to 4 watts input (positive output).
5 Build/Test Front-end Diplexer. A spectrum analyzer with RF generator or a network analyzer is recommended.
6 Build and test Band Detect Circuit. Do a simple DC test for this assembly. Power the Band Detect circuit with +12 V . With 0 Volts (grounded DET 2 M or grounded DET 70 cm inputs there should be no +12 V TX 2 M or +12 V TX 70 cm drive. Apply $\sim 90 \mathrm{mV}$ DC to these inputs and the +12 V TX 2 M or +12 V TX 70 cm drive should be available. The corresponding LED's should light up. The threshold is $\sim 82 \mathrm{mV}$.
7 Final Assembly:
Interconnect Front-End Diplexer,Band Detect Circuit,2M
Power Amp and 70cm Power Amp. The interconnect signal names should be consistent from one assembly to another. Check your wiring!
8 Final Test:
Power up with +12 VDC. This should be able to detect the RF input for each respective band (from~200mW to $\sim 4$ watts) and you should get close to the original power output that you saw in step 4. You should see the LED's light only when you apply RF input- if otherwise, check for instabilities.

## APPENDIX B. SOME TEST DATA

TABLE 6: Measured Values:(For Reference Only)

| PARAMETER | 2M DATA | 70cm DATA | Notes |
| :---: | :---: | :---: | :---: |
| Quiescent Drain Current: Only +12 applied. NO +12 V TX or RF input! | $\sim 1.1$ <br> microamp | ~11 <br> microamp | A very low drain current with no drive is a good indication. Not for potentiometer adjustment! |
| Quiescent Drain Current: +12 and +12 V TX ( 2 M or 70 cm ) applied. <br> NO RF input! | 56 mA | 228 mA | Your values may vary. This mode "Class C" does not require much quiescent drain current. Once you set the Quiescent Drain Current, do not adjust the potentiometer again. Do not adjust by gate voltage. |
| RF Power Input (Measured From HT using Diode Detector and 10 dB Pad) | $\begin{aligned} & \mathrm{LP}=0.365 \mathrm{~W} \\ & \mathrm{HP}=4.08 \mathrm{~W} \end{aligned}$ | $\begin{aligned} & \mathrm{LP}=0.33 \\ & \mathrm{~W} \\ & \mathrm{HP}=3.12 \\ & \mathrm{~W} \end{aligned}$ | ICOM IC-T7H |
| RF Power Output (Bird Model 4304) | $\begin{aligned} & \mathrm{LP}=18 \mathrm{~W} \\ & \mathrm{HP}=33 \mathrm{~W} \end{aligned}$ | $\begin{aligned} & \mathrm{LP}=6 \mathrm{~W} \\ & \mathrm{HP}=25 \mathrm{~W} \end{aligned}$ | Measured in Mobile Installation, Engine Idling |
| Calculated Gain | $\begin{aligned} & \text { LP~ } 16.9 \mathrm{~dB} \\ & \mathrm{HP} \sim 9.1 \mathrm{~dB} \end{aligned}$ | $\begin{aligned} & \mathrm{LP} \sim \\ & 12.6 \mathrm{~dB} \\ & \mathrm{HP} \sim 9.0 \\ & \mathrm{~dB} \end{aligned}$ | For Reference Only! Your results may vary. |
| Harmonics | $\sim-60 \mathrm{dBc}$ | $\sim-60 \mathrm{dBc}$ | (HP 8558B/182T) |

TABLE 7: RX PATH

| RX Path Data | RX Path Loss |
| :--- | :--- |
| 2M to Input Port | $0.61 \mathrm{~dB} @ 2 \mathrm{M}$ |
| 70 cm to Input Port | $1.1 \mathrm{~dB} @ 70 \mathrm{~cm}$ |

Notes:
[1] Three Fine Mice, QST,December 1986.pg 19
[2] Diamond Advanced Components, 450Washington St, Dedham,MA 02026 Also, Woody AK2F encouraged the author to document this project.

## APPENDIX B. SOME TEST DATA (CONTINUED)

SWEPT DIPLEXER RESPONSE:
The Red trace is $\mathrm{dB}[\mathrm{S} 21]$ for common port (J1) to the "Coax to 2M PA" line.
Likewise, the Green trace is db[S21] for common port (J1) to the "Coax to 70cm PA" line. The Black line is return loss for J1.

Some spot frequency values: (Your results may vary. These are exceptional!!)

| BAND | $\mathrm{db}[\mathrm{S} 11]$ | $\mathrm{db}[\mathrm{S} 21]$ | $\mathrm{db}[\mathrm{S} 31]$ | $\mathrm{db}[\mathrm{S} 22]$ | $\mathrm{db}[\mathrm{S} 33]$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 2 M | 23.8 | 0.14 | 38.2 | 22 |  |
| 70 cm | 25.4 | 51.9 | 0.19 |  | 32 |
